About the Editor

Jeffrey Jensen Arnett is a research professor at Clark University in Worcester, Massachusetts. During fall 2005, he was a Fulbright Scholar at the University of Copenhagen. He has taught at Oglethorpe University in Atlanta, the University of Missouri, and the University of Maryland. He received his Ph.D. in developmental psychology from the University of Virginia and was a postdoctoral fellow for 3 years at the University of Chicago.

Dr. Arnett is the author of *Emerging Adulthood: The Winding Road from the Late Teens Through the Twenties,* along with numerous scholarly articles in this area. He is also the author of the textbook *Adolescence and Emerging Adulthood: A Cultural Approach*. In addition to editing the *Encyclopedia of Children, Adolescents, and the Media,* he is the editor of the *International Encyclopedia of Adolescence*. He is also editor of the *Journal of Adolescent Research.*

Within the area of psychology and media, Dr. Arnett's primary interests include adolescents' uses of music and their responses to cigarette advertising. For the past decade, he has served as an expert witness on adolescents' responses to cigarette advertising in litigation against the major tobacco companies.

About the Associate Editors

Jane D. Brown is the James L. Knight Professor in the School of Journalism and Mass Communication at the University of North Carolina–Chapel Hill (UNC–CH). She is an expert on how the media are used by and influence adolescents' health and has studied the influence of the media on adolescents' tobacco and alcohol use, aggression and sexual behavior.

Brown is the coeditor and coauthor of four books, including *Sexual Teens, Sexual Media* (2002). Her research has been published in adolescent as well as media/communication journals, including the *Journal of Adolescent Health, Pediatrics, Journal of Communication,* and *Mass Communication and Society*.

She has served on the CHHD-W Population Sciences Committee (PSC) study section and the national boards of Advocates for Youth, The National Campaign to Prevent Teen Pregnancy, and the Trojan Sexual Health Advisory Council, and the selection committee for the William T. Grant Foundation's Young Scholars Program. She received a PhD from the University of Wisconsin–Madison.

Keith Roe is Director of the PhD School of the Faculty of Social Sciences at Catholic University of Leuven, Belgium. In 1991, he was appointed Professor of Communication in the Department of Communication at the university, and he served as chair of the department from 1996 to 2000. In 2000, he was elected Dean of the Faculty of Social Sciences, a position he held until 2003. He previously served as a Visiting Professor at the University of North Carolina–Chapel Hill and the Annenberg School for Communication at the University of Pennsylvania. From 1985 to 1990, he was Research Fellow at the University of Gothenburg (Sweden), including periods as a Visiting Scholar in Budapest and Humboldt University (Berlin).

Dr. Roe has led a significant number of large-scale research projects and has published widely on the media use of children and adolescents. He is currently joint editor of *Communications: The European Journal of Communication* and an advisory editor of *Poetics: Journal of Empirical Research on Culture, Media and the Arts; Young: The Nordic Journal of Youth Research;* and the *Journal of Children of Media.*

He earned a BSc in social sciences from Loughborough University in Leicestershire, UK, in 1971, an MEd from the University of Nottingham (England) in 1978, and a PhD from the University of Lund (Sweden) in 1983. In 1984, he was awarded the International Communication Association prize for the best PhD thesis of the year in mass communication.

L. Monique Ward is Associate Professor in the Department of Psychology at the University of Michigan. Her research interests center on children's and adolescents' developing conceptions of both gender and sexuality, and on the contribution of these notions to their social and sexual decision making. She is particularly interested in studying how children interpret and use the messages they receive about male-female relations from their parents, peers, and the media. Her work also explores intersections between gender roles, body image, and sexuality. Her research has been published in a diverse set of scholarly journals, including *Developmental Psychology, Journal of Research on Adolescence, Psychology of Women Quarterly, Journal of Sex Research,* and *Journal of Adolescent Research.* She serves on an APA-sponsored task force investigating the sexualization of girls.

She received a PhD in developmental psychology from the University of California at Los Angeles.

Barbara J. Wilson is Professor and Chair of the Department of Speech Communication at the University of Illinois at Urbana–Champaign. Before joining the University of Illinois, she was on the faculty at the University of California, Santa Barbara, for 12 years. Her area of expertise is the social and psychological effects of the mass media, particularly on youth.

Dr. Wilson is coauthor of *Children, Adolescents, and the Media* (Sage, 2002) and three book volumes of the *National Television Violence Study* (Sage, 1997–1998). In addition, she has published more than 50 scholarly articles and chapters on media effects and their implications for media policy. Her recent projects focus on preschoolers' attachment to media characters, parents' and children's fright reactions to kidnapping stories in the news, and children's attraction to media violence.

Dr. Professor Wilson currently serves on the editorial boards of seven academic journals. She has served as a research consultant for Nickelodeon, the National Association of Television Program Executives, Discovery Channel Pictures, and the Centers for Disease Control and Prevention. She earned a PhD from the University of Wisconsin-Madison.

Introduction

It was 1904, and G. Stanley Hall, writing his magnum opus on adolescent development, was concerned about rising crime rates among American youth. He discerned a variety of causes, but one key source of the problem was the media. As Hall saw it, a young man may be induced to commit crimes in part because "his mind becomes inflamed with flash literature and 'penny dreadfuls'" that portray crime as glamorous and heroic (p. 361). This was not the only problem of youth that Hall attributed to media influences. Johann von Goethe's 1774 novel, *The Sorrows of Young Werther,* remained popular in Hall's time—with pernicious effects, according to Hall. "The reading of romance has great influence on the development of youthful passion. Werther has created a distinct psychosis known as Wertherism" (p. 387).

Hall and his contemporaries could hardly have imagined the media environment that today's children and adolescents experience. The "literature" Hall worried about is still there, but now print media take a back seat to the newer, electronic forms: television, radio, recorded music, movies, mobile phones, electronic games, and the Internet. American children and adolescents use media for an average total of 6.5 hours per day, according to the Kaiser Family Foundation's landmark 2005 study of 8-to-18-year-olds—more time than they spend in school, far more time than they spend with their families. Totals are similar in other industrialized countries.

The fact that media use has become such a central part of the daily experience of children and adolescents all over the world makes this a propitious time to compile the *Encyclopedia of Children, Adolescents, and the Media.* Because the media children and adolescents use are so diverse, and because media use pertains to so many different aspects of children and adolescents' development, this was a monumental project, with the two volumes containing a total of 463 entries. There were 4 associate editors and 19 advisory board members, all of them outstanding scholars in media research. A total of 496 authors contributed entries.

Media are pervasive worldwide as part of children and adolescents' daily experience; accordingly, we sought to make the contents of the encyclopedia international. There are specific regional entries on Asia, Europe, and Latin America, as well as specific country entries for the two most populous countries in the world, China and India, and on Japan, which has been such an important contributor to children's media worldwide. Many of the other entries contain information drawn from a variety of countries.

Many people today, including many media researchers, share Hall's concern that the influences of media on children and adolescents are primarily negative, and this concern is reflected in the contents of the encyclopedia. Two of the largest topic categories are gender and sexuality (47 entries) and violence (31 entries). These entries show that the content of the media consumed by children and adolescents is dominated by sexuality and (especially) violence. Anyone who doubts Freud's theory that sex and aggression are the primary wellsprings of human nature need only spend a day perusing the media environment of the average child or adolescent. Toddlers and children enjoy cartoons wherein the main characters invent humorously creative ways of beating the snot out of each other; girls embrace the models of princess or tart (or princess-tart) offered by cartoon characters and pop stars; boys thrill to electronic games that involve pretending to kill bad guys and aliens; adolescents like best the movies and music that contain the most explicit sexual and violent content.

Although there is little doubt about the content of the media children and adolescents consume, the question of effects has been a challenging one in media research from its inception. Does sexual and violent content influence children and adolescents, or are the children and adolescents who are most attracted to sexual and violent content already different from other children, already more prone to sexual risks and aggression? Different scholars have different answers to this question, and the 37 entries on theories in this encyclopedia offer a variety of takes on it. Still, there is broad consensus among media researchers that media use is not merely correlated with children's development but also influences their development.

I admit that I originally came to this question as a skeptic, having learned in my training as a developmental psychologist to be wary of simple statements of cause and effect. However, eventually I was convinced of the effects of media by the accumulation of evidence—not just correlational or experimental studies but longitudinal studies, field studies, ethnographic studies, and natural experiments—and I believe that most thorough readers of this encyclopedia will be convinced as well, as they read through the entries describing the results of studies that used these different methods. Yes, children and adolescents make media choices based on their individual characteristics, and some more than others prefer sexual and violent content, but the effects of such content on their development are real, and we doubt them at our peril—and our children's peril.

Not only is sexual and violent content a source of concern. Also worrisome is the huge volume of advertising to which children and adolescents are exposed through the media. The 40 entries on advertising offer a wealth of compelling and unsettling details, and like the entries on sex and violence, taken together the entries on advertising leave little doubt about advertising's effects on children and adolescents (and here I can add that, as a parent of twin 6-year-olds who regularly clamor for whatever is relentlessly advertised on the Cartoon Network, I did not need to be convinced). Even schools, formerly places where the barrage of advertising in modern society was kept at bay, have now opened their doors to invite the barrage in, as shown here in entries on topics such as Sponsored Educational Materials and Commercial Television and Radio in Schools.

Given the many concerns about media use among children and adolescents, it is understandable that adults have organized in various ways to address those concerns. The encyclopedia contains entries on 22 advocacy groups, which comprise a wide range of national and international efforts to improve the quality (or at least minimize the damage) of the media content children and adolescents receive. There are also 39 entries in the area of public policy, showing the many approaches that have been taken nationally and internationally to control what media producers market to children and adolescents. In addition, 23 entries in the area of media education describe the methods that have been developed to teach children and adolescents to be discerning consumers of the media that surround them nearly all day every day, and to recognize and defuse media attempts to manipulate their desires, needs, and consumption habits.

Although the weight of opinion in the entries in the encyclopedia is decidedly in the direction of the concerns and potential negative effects of media, many entries show how children and adolescents benefit from their media use. Television may be mostly a vast wasteland saturated with sex and violence, but the best television provides children and adolescents with an entertaining educator and opens their minds and imaginations to new worlds. Music provides children and (especially) adolescents with materials for building personal and group identities and helps them to manage unruly moods. Movies can provide wonderful, inspiring stories. Mobile phones and email allow children and adolescents to connect to a broad network of friends and family much more often than was possible in the past. The Internet is a portal to an infinite store of information about every imaginable topic. Even print media have retained their power to inspire children and adolescents, as the recent *Harry Potter* craze has demonstrated. Who could have predicted that children and adolescents all over the world would become riveted to a series of 500+ page books about a boy who attends a school for wizards? This example helps remind us that media are, at their best, wonderful sources of enjoyment for children, adolescents, and the rest of us.

Although we sought to be as comprehensive as possible in putting together the two volumes of the encyclopedia, we decided early on not to include entries on specific media characters or performers. There were three reasons for this. First, if we had opened the door to this, it would have been difficult to stop (once we had an entry for Metallica, how could we have denied an entry to Megadeth?). Second, notwithstanding the

enduring popularity of characters such as Tom and Jerry or performers such as Madonna, most media characters and performers popular among children and adolescents have a rather short time in the spotlight. (There was a popular singer a few years ago, Britney something—remember her?) They come and go, and entries on them would already seem dated by the time the encyclopedia was published. Third and most important, the focus of the encyclopedia is on children and adolescents' experiences with media rather than on the specific media products they use. If boys are avid players of the electronic game *Grand Theft Auto*, what is important about this, for our purposes, is their avid involvement in a highly violent electronic game, not the fact that the specific game is *Grand Theft Auto.* Next month or next year, another violent electronic game may come along and supersede *Grand Theft Auto* in popularity, but the important issues pertaining to boys' involvement in violent electronic games will endure.

In closing, I would like to thank the many people involved in producing the encyclopedia. First, my eminent associate editors, Jane D. Brown, Keith Roe, L. Monique Ward, and Barbara J. Wilson. They did a fabulous job of helping me assemble the hundreds of authors for the encyclopedia. Each of them edited many of the entries, and each also contributed at least one entry. Second, the 19 advisory board members, who suggested many of the entries we included in the encyclopedia and who were also key in assembling the authors for the project. It was a great honor to work with such a stellar group of media scholars. Third, at Sage Publications, the development editors Eileen Gallaher and Diana Axelsen, and Beth Bernstein, the production editor; all of them were extraordinarily capable in administering the project and getting all the entries into good shape, and they were delightful to work with.

Finally, I would like to dedicate my work on this encyclopedia to the memory of my mother, Marjorie Littlefield Arnett, who entertained us throughout my childhood with a wry running commentary on the stupidity and venality of most advertising, no doubt providing me with a "media education" that endures to this day. This is for you, Mom.

—Jeffrey Jensen Arnett
Clark University

ACTION FOR CHILDREN'S TELEVISION (ACT)

From 1967 until 1992, Action for Children's Television (ACT) served as an advocacy group that fought for high-quality children's television programming. ACT's first meeting was held in December 1967 in the Boston home of Peggy Charren, the group's driving force. The group was formally constituted in 1968. Although ACT was often portrayed as "just" a group of housewives, it was, in fact, built on the corporate model, with annual reports, yearly audits, and a board of directors with legal and financial expertise. Its members, primarily women, represented a wide range of professional experience. ACT was disbanded in 1992 when Charren stepped down as director. However, during its 25 years of activity, the organization was central to the debates on children's television.

During its first years, ACT commissioned research, wrote grants, and gained national attention. One early event involved the picketing of a local television station to restore the popular children's program, *Captain Kangaroo.* The event, complete with entertainment, children, and balloons, led to the return of the program and national media coverage for ACT. Within two years, the group had grown to more than 1,000 members and had formed alliances with other national organizations, such as the National Parent Teacher Association.

The organization's most significant contribution began in the early 1970s, when it filed a petition for rule making with the Federal Communications Commission (FCC) outlining the problems with children's television and asking for (1) no sponsorships or commercials on children's television; (2) no host selling or product tie-ins during children's television; and (3) a minimum of 14 hours per week of age-specific programming. This petition was given the docket number 19142 and remained open for almost 14 years. As a result, for the first time in broadcast history, the FCC held broadcasters accountable for children's programming. From Docket 19142 came a series of task forces, hearings, and memoranda. But whereas previous FCC commissioners had made some attempts to regulate children's television, Mark Fowler, chair of the FCC in 1983, believed in reliance on marketplace regulation—change brought about by market demand rather than by government regulation. Finally, after little definitive action, the docket was closed in December 1983. Although little regulation was instituted while the docket was open, ACT had established the importance (and the lack) of quality in children's television. Once the docket was closed, the debate moved to Congress. Here, over a period of nearly 10 years, ACT lobbied representatives, urging them to introduce legislation in the Senate and the House obligating broadcasters to fulfill their public service responsibilities to the child audience. Although a bill that passed in 1988 was subjected to a pocket veto by President Reagan, the Children's Television Act (CTA) was eventually passed in late 1990 and put into law.

Whereas other advocacy groups called for control of content, ACT saw such control as a violation of First Amendment freedoms. At the core of ACT's argument was a belief in broadcasters' legal responsibility to

serve the public according to the 1934 Communications Act, which allowed and licensed broadcasters to use the airwaves in return for serving the public's interest. ACT's attempts to bring change both through the Federal Communications Commission and later through Congress were grounded in this philosophy. The Children's Television Act of 1993 resonates with the 1970 petition, which asked for age-specific programming, a commitment of programming hours, and limits to advertising on children's television, and was based on a belief of broadcasters' responsibility to the child audience.

ADOLESCENTS, DEVELOPMENTAL NEEDS OF, AND MEDIA

Adolescence is marked by a number of physical, cognitive, and social changes that interact to create a number of developmental needs specific to this age group. As adolescents seek to define themselves independently of their parents, they often turn to media as sources of self-socialization and of messages about their identity in terms of gender, sexuality, and ethnicity. Although parents and peers remain influential during this transition, this entry focuses on adolescents' use of media to navigate developmental changes and cope with the daily difficulties of being teenagers, and on the role of media in shaping adolescents' development of identity and autonomy.

ADOLESCENT TIME SPENT WITH MEDIA

During adolescence, children spend less time with parents and an increasingly large amount of time by themselves, during which they often participate in unsupervised media, such as television, music, and video games. The typical American adolescent listens to music approximately 4 hours a day and watches television approximately 2 hours a day. In addition, 75% of adolescents have access to computers, 61% report surfing the Internet, and 70% of adolescent girls read popular teen magazines. In combination, these media consume approximately 8 hours of adolescents' time each day. Given the vast exposure to media influences, research suggests that media serve a number of developmental purposes for adolescents beyond that of mere entertainment.

DEVELOPMENTAL NEEDS OF ADOLESCENTS

A great deal of research has examined the developmental transitions that children experience as they enter adolescence. These changes can be loosely placed into three main categories: first, physical changes, such as the increased hormonal levels and sexual development characteristic of puberty; second, advances in cognitive development, characterized by increases in abstract thought; and third, social changes, such as changes in relationships with parents and peers. These three areas of adolescent development interact with one another to make adolescence an age of transition characterized by unique developmental needs, for some of which American adolescents may rely more heavily on media as a source of self-socialization. This entry focuses on adolescents' identity development and need for increased autonomy, and on the ways that adolescents use media to facilitate these goals.

ADOLESCENT IDENTITY FORMATION

A primary challenge undertaken during adolescence and emerging adulthood is the formation of an identity distinct from one's parents. This does not necessarily mean that the adolescent will choose an identity that conflicts with that desired by parents, but it does suggest that many adolescents will experience some period of exploration and experimentation as they search for a unique place in the world. In their search

for identity, adolescents may intentionally or unintentionally turn to the media for an understanding of what is socially acceptable. A few of the most salient aspects of identity formation for which adolescents use media as a source of socialization are gender identity, sexual identity, and ethnic identity.

Gender Identity

The media send very clear messages of what it means to be a man and what it means to be a woman, and sometimes offer exaggerations of gender stereotypes that profoundly influence children's understanding of gender and gender roles. Television sends messages about gender in a number of ways. One message is conveyed by the sheer underrepresentation of woman on television; another by the portrayal of stereotypic occupations of women and men. Although this has changed slightly over the past 20 years, commercial television provides youth with many traditional views of what is masculine and what is feminine and may contribute greatly to the occupational aspirations of teenagers. Research suggests that when gender-stereotyped television is introduced to an area that previously did not have television; the youth in that area become more gender stereotyped. Although this may be true, adolescents may also seek non-gender-stereotyped information on television that leads to emulation of a role model who defies gender stereotypes, such as a female athlete or a male schoolteacher.

In addition to television, video games and magazines may be used by adolescents as a source of information on gender identity. Nearly 99% of video games are targeted toward males and feature violence, loud sound effects, and rapid movement. This includes educational software that emphasizes male themes and plays to the strengths of males. Teen magazines also send clear messages about gender and what it means to be masculine and feminine. Teen magazines set guidelines about body image, fashion, and beauty for young girls. Although girls are generally the target of teen magazines, boys are also increasingly susceptible to the messages about male body image and male orientation toward females that abound in magazines for men and boys. Both males and females seeking to understand how to behave can access multiple sources of media for clear, albeit often misleading, information on gender identity.

Sexual Identity

With the onset of physical changes during adolescence, youth look to media for information about their own sexual identity and sexual behaviors. This may be particularly true for adolescents who are less sexually experienced and who may not be receiving the answers they seek from other socialization sources, such as parents. Magazines provide ample information about what relationships should entail and how one should behave in a sexual relationship. Music with sexual themes and computer or video pornography are also media sources used by adolescents to gain knowledge about sexual roles. Girls commonly turn to romantic television or books to gain ideas of what love and sexuality should look and feel like, and these sources may provide youth with skewed views of sexuality and dating, setting unrealistic expectations.

Although media are a rich source of sexual information for adolescents, they may provide adolescents with sexual values that are contrary to parental values. For example, research has found that the majority of prime-time television contains content of a sexual nature; in most cases, sexual actions and language occur between unmarried couples with little reference to contraception or the potentially negative consequences of sexual activity, such as sexually transmitted diseases. Given that parents often do not provide adolescents with sexual information and that adolescents may feel uncomfortable discussing issues of a sexual nature with their parents, media are an important socialization agent for adolescents seeking information about their sexual identity.

Ethnic Identity

Another salient aspect of adolescent identity development is ethnic identity—adolescents' expression of affinity and pride in their cultures of origin. Adolescents' use of media as sources of information regarding ethnicity may be particularly significant for those who have limited real-life exposure to peers of different ethnicities. Much like gender identity, information provided by the media on ethnic minorities may be highly stereotypical or, conversely, may provide information that combats racial stereotypes. Messages on ethnic identity are prevalent in adolescent music as well as commercial television and movies. In general, television underrepresents the number of minorities in real life and sends messages

that do not reflect the diversity in America. As a result, adolescents may construct ideas about the unimportance of certain ethnic groups, as well as images of how people of other ethnicities are likely to behave.

If adolescents are not exposed to ethnic diversity in their daily lives, media may provide them with the information they seek. The frequent portrayal of minorities as victims or in violent roles on television may encourage intolerance and fear on the part of European American teens, as well as providing, for minority youth, negative stereotypes of what they should aspire to become. Research has found that movies have a great influence on how adolescents perceive those of differing ethnicity. For example, movies that portrayed a minority group in a consistently favorable or unfavorable manner were found to make strong impressions on children of all ages, in many cases altering perceptions of people of another race. Minority adolescents also rely heavily on television to provide them with messages, which may or may not be accurate, about European Americans and the values espoused by the majority culture.

AUTONOMY

The adolescent search for an identity distinct from that of parents is characterized by a desire for increased autonomy. Although this desire may be perceived as rebellion, adolescents often turn to media to express their individuality or autonomy. This is often reflected in adolescents' use of private media, which usually takes place in the solitude of their bedrooms. Research suggests that music is a particularly important way in which youth choose to express their differences from their parents. So what may seem like "jungle music" to adults is merely a means by which adolescents exert some control over their growing need for autonomy. In addition, this time alone is used as a means of identifying with a peer culture and as a respite from the emotional roller coaster common during adolescence.

Peer Identification

As adolescents spend less time with parents, they spend more time with peers. Media are sometimes used by adolescents as a means of identifying with their peer group and expressing their autonomy as a peer culture distinct from that of adults. The existence of a distinct peer culture is easily recognized by adults who may seem unaware of popular television programs watched by teens, the latest video game craze, or the most recent music release. The use of media, particularly music, may help adolescents feel a connection to peers in general, regardless of actual association, or may define a particular peer group or crowd. Another way in which adolescents learn about youth culture is through advertisements encouraging them to buy the latest clothing, beauty product, or breakfast cereal. Adolescents are exposed to more than 20 commercials per hour on television and spend $67 billion a year on commercial products. Whether it is a famous athlete advertising breakfast cereal or the latest pop star promoting a particular clothing line, adolescents gain information about peer culture from media advertisements and use this information as a guide to what is popular among youth.

Coping

Research suggests that, as adolescents distance themselves from their parents, their sense of self and, in turn, their self-esteem decrease. Adolescents struggle with who they think they are and who they want to become, and this struggle is often characterized by increased emotionality. Much of this search for autonomy and a sense of self occurs while the adolescent is alone, which is often a time of loneliness and depression. As a result, many adolescents turn to media as a way of coping with the loneliness, frustration, and anger prominent during adolescence. Adolescents use solitary television viewing both to express their autonomy by watching what they choose and to detach themselves from the emotional rigors of the day. The major portion of solitary media time is spent listening to music—65% for early adolescents. Many adolescents report using music not only to unwind but also to explore fantasies, purge anger, express their individuality, and think about relationships as expressed in popular love songs. Research has focused specifically on adolescents' (particularly adolescent males') use of rock or heavy metal music to resonate with their own feelings of frustration and rage. In many cases, adolescents claim that rock music actually helps them to feel happier or improves their emotional state.

ADOLESCENTS, MEDIA PORTRAYALS OF

Media portrayals contribute to the public's view of teenagers and to teenagers' views of themselves. Different media present very different pictures of adolescent life. This entry considers media portrayals of youth in the news, on dramatic television, in teen magazines, and on the Internet. Although research that looks specifically at adolescents is relatively sparse, some reasonable, though sometimes time bound, conclusions can be drawn.

TEENAGERS IN THE NEWS

In a 2000 study of television news, the Center for Media and Public Affairs found that adolescents received relatively little coverage, with youth-focused stories constituting about 8% of local news and 4% of national news. This research, by Amundson and his colleagues, is one of approximately a dozen studies that have looked at portrayals of adolescents in print and TV news. Across various media (print vs. broadcast), foci (local vs. national coverage), and locales, a persistent finding is that bad news dominates the youth-news agenda. In most cases, crime is far and away the most common focus of news stories about teenagers, although the relative dominance of stories that portray teens as perpetrators, as opposed to victims, appears to fluctuate over time, medium, and locale. Overall, negative, event-based coverage dominates the coverage of teens: Crime, accidents, and risky behaviors—such as drinking, drug use and sexual abuse—accounted for nearly two thirds of all stories in the Amundson study. There are some indications that greater thematic balance can be found on national TV and in some local papers than on local TV news. However, the relative incidence of violent teen crime in local papers still tends to far outstrip its real-world occurrence. For instance, one study of major newspapers in California found that 25% of all youth stories were about youth violence at a time when 3% of young people in the state either perpetrated or became victims of violent crime.

Researchers have also located some noteworthy sex-, age-, and race-based differences in news portrayals of adolescents. Amundson and his colleagues found that males were about three times more likely than females to be the subjects of TV news stories about teens. This overrepresentation of males also appears in crime news, where 80% of TV crime stories about teens involved males. When females were represented, however, they were nearly as likely as males to appear in crime stories. High-school-age teens appear to be covered more frequently than middle-school or post-high-school youth, and, as teens get older, crime and risky behavior increasingly dominate the picture. Whereas crime is prominent in coverage of all demographic groups, African Americans and Hispanics tend to fare worse than their white counterparts. Amundson and his colleagues found that crime stories accounted for more than 50% of the segments in which nonwhite youth appeared, versus 35% for whites. In a 2001 review of the research on all forms of media coverage of youth violence, Dorfman and Schiraldi concluded that news coverage of crime, especially violent crime, is not proportionate to its occurrence and that it presents a distorted view of the percentage of overall crimes committed. They also found that minority perpetrators were overrepresented in crime coverage, whereas minority victims were underrepresented.

The high prevalence of crime in news portrayals of youth has raised concerns about the potential effects of this coverage on public perception and, ultimately, on crime-related policies. Numerous studies have shown dramatic increases in crime coverage during periods when actual crime rates are steady or in decline. Correlational studies have tied the prevalence of crime coverage to public perceptions of actual crime rates and to support for policies that punish the perpetrators but ignore deeper societal roots of crime. It is not only the overrepresentation of crime news that concerns researchers; it is also the form of this coverage. Several studies have shown that the overwhelming majority of crime stories focus on individual criminal acts and largely ignore discussions of causes and solutions. By

The 1946 film *Margie* held on to playful mythologies about teenage life before later post-war movies confronted darker adolescent issues. As evident in this ad, the story nostalgically celebrates its heroine's spirited days in high school during the Roaring Twenties through her crush on a teacher and her conflicted recognition of women's rights. Many movies about adolescents employ a similar sentimental appreciation of earlier days when teenage life was supposedly sweeter, even if the teens are far from carefree or innocent, as in *Splendor in the Grass* (1961), *The Last Picture Show* (1971), *The Outsiders* (1983), *School Ties* (1992), and *Lords of Dogtown* (2005).

omitting the broader public health context in which individual acts are situated, news stories may reinforce a consistent human bias toward attributing the causes of youth crime to dispositional traits of youth offenders and toward ignoring the societal conditions that lead some teens to commit criminal acts and others to avoid them. Indeed, experimental studies have shown that stories that focus on the characteristics of individual actors tend to forestall consideration of broader societal causes of and solutions to social problems. Some efforts are being made to bring a public health, or epidemiological, perspective into the newsroom and to refocus the coverage of youth crime on the environmental factors—poverty, access to guns, substandard schools, dysfunctional families, lack of community policing, and so forth—that promote higher crime rates.

In addition to their appearance in such "bad news" stories, teens frequently enter the news window through coverage of educational funding, policy, and practice and, to a lesser extent, in their roles as athletes. Teens also figure in stories on health issues, such as school immunization programs, nutrition, and obesity problems among youth, as well as in stories about individual health problems. Much less frequent are stories about teens engaged in community service; and, of the more than 8,000 local news stories analyzed by Amundson and his colleagues, fewer than 10 dealt with employment- or career-related issues of teenagers. In that study, teen females were about 50% more likely than males to appear in family and lifestyle stories, and no nonwhite youth were pictured or explicitly mentioned in stories about health.

The news portrayal of teens depends, of course, on genre. In business segments and sections, teens are most often cast as consumers. In contrast to the prevalent hard-news portrayal of teens as either perpetrators and risk takers or as vulnerable victims, the business news depicts teens as a powerful and virtuous force, one that makes or breaks the latest movie, gaming technology, or clothing line. The business news is also the place where one is most

apt to find the entire cohort of 13-to-19-year-olds grouped in terms of its age-based identity. Whereas hard-news stories often describe *individual* members of this group according to their status as "teenagers," the business perspective characterizes this collectivity as the "teen market." From this viewpoint, it is the product preferences and buying habits of teens that distinguish this group from other age-based cohorts and that become the defining characteristic of adolescent identity.

The overall pattern of news coverage shows that, outside of their roles as criminals, risk takers, and athletes, and in their collective guise as a vital market segment, teens in the news are rarely portrayed as proactive social agents. They tend to be shown, rather, as victims or potential victims of social policies or, less frequently, as beneficiaries of social programs. The "beneficiary" story tends to focus on organizations and programs that rescue and revive at-risk teens. Similarly, in coverage of education, teens tend to serve, not as social actors in worlds of their own, but as exemplars of groups of students who will be affected in one way or another by the decisions of powerful others.

This bird's-eye view of the largely grim and powerless roles afforded teenagers in their appearances on the stage of current affairs has implications that go beyond the stereotypes and policy preferences such stories may foster in adult readers. Teens themselves spend a small and declining portion of their time reading newspapers, and when they do, they prefer comics, sports, and entertainment sections to hard news. Researchers, meanwhile, have suggested links between the early adoption of news-reading practices and the subsequent development of news-reading habits, political sophistication, and intentions to become civically engaged. Whether the portrayal of disempowered teens presented in the news discourages early news reading is a question that researchers might fruitfully address.

Efforts to incorporate a public health perspective into coverage of teens may help boost consideration of the causes and cures of the problems faced and instigated by adolescents. However, the general tendency to portray teens as problems reflects a broader tendency of news media to focus on conflict and elite points of view. The civic journalism movement represents one attempt to refocus the lens through which journalists view their respective news beats in ways that not only bring solution-focused stories into the news repertoire but also allow audiences, including youth, to have a say in setting the news agenda. Whether this initiative is changing the youth beat in ways that also draw young viewers and readers and into the fold waits to be seen.

TEENAGERS ON TELEVISION

Among the hundreds of content analyses of entertainment television, only a handful have focused on the portrayal of adolescents**.** The dearth of research in this area is surprising given the strong rationale provided by historically dominant models in the media effects literature, notably Gerbner's cultivation theory and Bandura's social learning theory. The focus placed by cultivation research on the beliefs formed about *others* suggests a need to analyze the influence of TV's portrayal of teens on the beliefs that both teens and non-teens form about real-world teenagers. Bandura's focus on vicarious modeling suggests the need to analyze how TV's portrayal of teens influences teenagers' *own* attitudes and behaviors: As experimental research has shown, teens are more apt to emulate the behavior of models with whom they share certain similarities, such as age. Generalizations based on the data that do exist are time bound, impressionistic, and/or restricted to the particular facets of teenage life that researchers have chosen to examine.

Signorielli examined several characteristics of adolescent characters on prime-time TV in an analysis of aggregated data for the years 1969 through 1985. She found that adolescents were consistently underrepresented relative to their real-world counterparts: Whereas the 10-to-19-year-old age group constituted roughly 15% of the U.S. population, this cohort of TV characters accounted for about 8% of the prime-time population. The male–female ratio in prime time during this period tended to favor males in all age groups: Among teenage characters, males outnumbered females by about three to two. Signorielli also analyzed the relative chances of being a perpetrator versus a victim of violence. She found that adolescents, particularly females, were proportionately more likely to be victimized than were middle-age characters. The author interprets these findings as measures of social power and status, concluding that, relative to middle-age adults, teens—particularly females—are neglected and devalued on television. In this respect, Signorielli's conclusions echo those of Peck, who had previously concluded that TV's youth are played for laughs, shown as subordinate to adults, or portrayed as victims.

In another analysis, however, Signorielli compared role type (good vs. bad; successful vs. unsuccessful).

Here, she found that adolescents were more likely than middle-age characters to be presented as good and as successful. Family life was also found to be particularly important for younger adolescents, with 8 of 10 characters between the ages of 10 and 14 shown interacting with family members during prime-time hours. Thus, whereas teen characters were relatively sparse and powerless, they were also shown as benign, family oriented, and effective in their endeavors.

A study by Wilson and her colleagues analyzed programs aired between 6 a.m. and 11 p.m. across 23 different channels in 1995. This research was designed to examine whether the characteristics of violence on television are those that psychological theory suggests are likely to prompt viewers to model the violent acts. It nonetheless yields some interesting data on the characteristics of TV's portrayals of violent teenagers. Across the 2,500 hours of television included in this sample, teen perpetrators aggressed about once every 2.5 hours, and 7% of all offenders were youth between the ages of 13 and 20. Of these teen perpetrators, 81% were male, 56% were "good" characters, and 60% of their victims were other teenagers. These data do not reveal the likelihood of teen characters engaging violent or aggressive acts. However, these and other data collected in the study suggest that the characteristics of TV's violent teens are those likely to provoke peer-directed aggression by male teen viewers.

Wilson's data also reveal that viewers are most likely to find violent teenagers in movies (44% of all teen violence) and children's programs (32%) and are much less likely to encounter teen violence in drama (7%) or comedy (2%). Thirteen percent of teen violence occurred in music videos. These genre-related differences indicate that viewers' take-home message about the characteristics of teenagers depends very much on the programming preferences of viewers.

In one of the few studies to examine a broader range of teenage characterizations on TV, Heintz-Knowles examined prime-time entertainment programs airing on the six broadcast networks (ABC, CBS, NBC, Fox, WB, and UPN) in 1999. The author looked at the kinds of problems facing prime-time teens, the way these teens deal with problems, the activities they tend to engage in, the youth-oriented issues they tend to discuss, and their rates of alcohol and drug use.

The problems dealt with by teens tended to relate to romance, friendships, and family issues, whereas problems related to work, learning, and personal health were rare. Violence and drugs accounted for a very small portion of the problems faced by teenage characters: Only 4% of youth characters were involved in story lines in which the central conflict was an act of violence.

The main problems faced by teens were satisfactorily solved about 50% of the time. The rest of the time, the problem was either left unresolved at the end of an episode or resolved in a fashion that ran counter to the character's wishes. In about four of five successful problem-solving attempts, the solution was the result of a collective effort, with friends, family, teachers, and other adults chipping in. Just who these teen problem-solvers relied upon depended upon problem type. For instance, peers were much more likely than adults to be recruited to help with problems related to friendships. Teen characters were most often shown to solve problems without adult help in teen-centric programs. Generally, teens often showed concern for those in need of assistance.

As primary activities, teens in the prime-time programs analyzed by Heintz-Knowles most often socialize at school and "hang out" away from school, usually in characters' homes. They are frequently shown doing schoolwork but nearly always as a background activity. Work, chores, and making out are other common background activities. Although 9% of the characters are shown drinking or using drugs, these episodes are clustered in 5 of the 45 programs included in the study. About 12% of characters participated in some form of extracurricular activity.

Finally, the discussions of youth-oriented issues engaged in by teenagers were dominated by issues of romance, family, social pressures, sex, and school. Societal-level problems were notably absent from these discussions. On a similar note, social institutions such as government, business, and social agencies were hardly visible in prime-time programming.

In a study of teens' favorite dramatic programs, Strange, Christenson, & Roberts focused on those aspects of programming related to significant developmental tasks and risks of adolescence. They examined, inter alia, relationships with parents and with mentors, orientation toward learning and toward the future, sex and romance, body image, fitness, and mental and physical health. Although limited to the 2001–2002 season under study, these data allow several generalizations about the portrayal of teens on the programs most popular among 12-to-17-year-old viewers.

Today's TV families confront more teen-relevant issues than the TV families of old: Teen sex, underage

drinking, thong underwear, abortion, and coping with a parent's remarriage all make appearances as central issues in the plots of teen TV. Although parent-teen conflict is prevalent, it tends to occur in an environment of constructive engagement rather than alienated detachment. Cases of outright dysfunction tend to appear as satire (e.g., *The Simpsons, Malcolm in the Middle*) or to be held up as regrettable aberrations (*ER, CSI*) rather than models to be emulated.

Teenage characters do enter into mentoring relationships with nonfamilial adults; however, these relationships tend to be brief rather than long-term and are clustered among just a few of teens' favorite shows (especially *7th Heaven* and *Boston Public*).

Schools are a common backdrop in teen-centric programs. The most common orientation to schooling portrayed on these programs is one of commitment to a required endeavor, one that is sometimes deemed important but is rarely viewed as desirable. Only a few programs (e.g., *Malcolm in the Middle*) show teens to be bored outright with school; however, depictions of teens who truly enjoy learning (e.g., *Gilmore Girls*'s Rory) are even less common. Little focus is placed on what is being learned or on the relevance of the subject matter to society or to teens' lives. *Boston Public* provides one exception, in which the topics students engage in their classes sometimes spill over to the issues they confront in their lives.

The college plans of teenagers are discussed in about 15% of episodes in which teen characters are present. However, the kinds of career exploration one might hope to see in adolescents were largely absent from these programs. More generally, little attention is paid to the future-directed concerns of teens in the programs they most frequently watch.

Teens' favorite programs acknowledge the reality of teen sexual activity but offer mixed messages about teen sex and romance. Previous intercourse by teenage characters was referred to in about 18% of the episodes studied. The messages inherent in these portrayals are highly inconsistent. "Lessons" range from "Virginity is a sign that a boy is a loser" to "Teens don't need to be sexually active to be cool." The programs depict attractive teen role models who intentionally wait to have sex, those who just can't wait to have sex, and those who don't wait to have sex. Discussions of safe sex are largely lost between programs that ignore teen sex and those that treat it as a given.

As in most of television, teen TV programmers tend to cast svelte, attractive females and, to a lesser extent, handsome and "buff" males: No heavier-than-average characters were cast in leading roles in teens' favorite programs during 2001–2002. Teens are rarely depicted engaging in physical exercise. Still rarer are expressions of its many benefits, be they the pure enjoyment of sports, the camaraderie, or the payoffs in terms of health and appearance.

The teens on teen TV are shown to grapple with troubling life predicaments, but rarely do they experience serious mental disorders. Those that do tend to play visiting roles on crime shows like *CSI,* where they take their place alongside pathological criminals of all ages. The incidence of the mental disorders that most frequently beset teenagers appears to be significantly lower in the world of TV teens than in their real-world counterparts. Although some experts have worried that stories provide alluring models of the sorts of "oppositional defiance" often associated with the teen years, this worry finds little support in teens' favorite TV programs. Whereas a few characters do exhibit such anger, resentment, and spite, such states are typically presented as ones to avoid rather than emulate. Finally, this study did find a few instances in which young characters consulted mental health professionals: These portrayals were about equally likely to support as to counter the stigma associated with counseling.

Teens tend not to be politically inquisitive or politically involved. They are rarely shown volunteering or engaging in social service activities. Their lives are centered around school, home, and the social activities of peer groups; when these spheres overlap the civic sphere, it tends to be in small-town environments, like that found in *Everwood,* where the private and public are naturally intertwined.

For those interested in assessing the effects of television—on modeling, group norms, social comparison, and the like—a strong caveat must accompany generalized descriptions of TV's teens. The ongoing proliferation of programming choices has led to a plethora of viewing niches, each with its own profile of teenagers. For instance, the TV diets of male and female teenagers differ significantly from each other, as do the portrayals of teens on the programs they tend to view. Based on viewing data, a case can be made that the models of teens on shows watched by teenage girls (e.g., *Gilmore Girls, 7th Heaven)* are more conducive to healthy development than those on the shows watched by teenage boys (e.g., *Family Guy, Tick, The Simpsons*). These differences are most pronounced on cable programs, where the trend toward niche

programming is stronger. Top shows for girls during the 2002–2003 season were programs like *Lizzie McGuire, Sister-Sister,* and *Clueless.* Boys, on the other hand, preferred shows like *X-Men, Jackie Chan,* and *Justice League.* Group-based differences in programming diets are also apparent when comparing the top TV draws for black, white, and Hispanic teenagers, and when comparing the favorite programs of teenagers and adults. Whereas teen characters are much less likely to populate the programs preferred by adults, those that do appear are more likely to be of the troubled variety found on *CSI* than the wise and gregarious sort found on *Gilmore Girls.* In sum, the image of teens that particular viewers take away from their TV experiences depends very much on what they watch.

TEENS AS REFLECTED IN TEEN MAGAZINES

Whereas the development of niche programming is a recent development in television, magazines have long catered to the distinctive interests of teenagers, particularly teenage girls. Since the 1940s debut of *Seventeen,* teen-centric magazines have been a staple of the American girl's media diet. Although boys spend as much time as girls reading magazines, boys' interests are captured by specialized fare that caters more to particular hobbies, such as electronic gaming and sports. No magazines targeted toward teenage boys have approached the market penetration of girls' magazines such as *Seventeen, Cosmo Girl,* and *Teen People,* which are regularly read by between 50% and 70% of teenage girls in the United States.

Research has focused on magazines targeted toward teenage girls and has been motivated primarily by concerns surrounding sexuality and sex-role socialization. Although this research has rarely looked exclusively at the portrayals of the adolescents in teen magazines, the narrow targeting of these publications suggests that their content can be viewed as a portrayal, if not an accurate and balanced reflection, of teen interests. On this reading, the interests these magazines cater to—and likely bolster—are dominated by fashion, beauty, celebrities, romance, and sex. In one study of the most popular teen magazines from the late 1980s through the mid-1990s, Walsh-Childers and her colleagues also found a substantial focus on messages related to sexual health—especially contraception, pregnancy, and STDs—and sexual decision making. During the 1993–1996 period, teen girls' magazines devoted about the same number of column inches to articles whose primary focus was sexual health (42 inches per issue) as they did to articles whose primary focus was sex (45 inches), a category that included articles about whether or not to have sex. The authors also found, however, that the space devoted to non-health sex-related content had increased from a 1986–1989 baseline at a rate much faster than that devoted to sexual health coverage. Teens, then, are implicitly portrayed as sexually active or as grappling with the benefits and risks—physical and emotional—of sexual intercourse. Surveys cited by Walsh-Childers and her colleagues indicate that high-school-age girls seek out this information, which, a sizeable majority report, is not available to them elsewhere. A broadening of the teen magazine market in the late 1990s included the launch of titles aimed toward smaller demographic niches, including ethnic groups, and broader interests than those reflected in fashion, beauty, and romance titles like *Seventeen.*

TEENS AND THE INTERNET

The increasing popularity of the Internet has brought with it a considerable broadening of the images of youth that are available to all audiences. Commercial websites mimic the offerings of the print versions of newspapers and magazines, and "podcasts" of radio and TV fare are allowing on-demand access to the vast libraries of fare available in those media. Added to these traditional offerings are images of youth that represent a variety of portrayals and viewpoints that parallels the diversity of teenage life to an extent not seen in earlier media. Written by teens, for teens, and often about teens, e-zines can be found for "grrls" of all sociopolitical persuasions. Personal Web pages and blogs allow the broad dissemination of autobiographical images and expressions of self in the form of photos, biographical descriptions, essays, and poems. Virtual communities and online social networks provide a media space in which teens locate others with similar interests and which are increasingly seen as lenses through which both teens and adults form their impressions of teenagers. This explosion of teen-centric expression makes it increasingly difficult to generalize about the portrayal of adolescents in the media as these portrayals become ever more varied. In similar fashion, as teens increasingly author their

own portrayals and audiences settle in on this or that programming niche, it seems likely that the images of teens held in popular consciousness will grow progressively more diverse.

ADOLESCENTS, MOVIE PORTRAYALS OF

During the first decades of cinema, adolescents sporadically had roles in many American films, such as *Seventeen* (1916), *Harold Teen* (1928), and *Wild Boys of the Road* (1933). However, a more coherent genre of teen film was just beginning to form when young stars like Deanna Durbin and Mickey Rooney achieved fame in the late 1930s. Durbin had such hits as *Three Smart Girls* (1936) and *That Certain Age* (1938), and Rooney played popular teenager Andy Hardy in a franchise that started with *A Family Affair* (1937) and continued for many years. These films largely showcased the plucky nature of youth, avoiding such

realistic yet controversial teen topics as sex, alcohol and drug use, and crime. Then, as the Depression era gave way to World War II, more films about troubled teens began to appear. The most prominent example was an unlikely franchise about a group of hardened if often honorable delinquents, the Dead End Kids, which began in 1937. Still, it was after the war that Hollywood began to address serious youth issues more consistently, and with adolescents emerging as a social force, they also became the target audience of the film industry.

America's fascination with juvenile delinquency became evident in two 1949 films, *City Across the River* and *Knock on Any Door,* both directly addressing the problem of teen crime. Films of the 1950s would expand upon these themes in sensational fare such as *On the Loose* (1951) and *Problem Girls* (1953) and in more respectable productions such as *Rebel Without a Cause* (1955) and *Blackboard Jungle* (1955). *Rebel* spoke about current teen tensions in sincere tones rather than didactic monologues, showcasing youth trying to discover themselves and declare their identity within the prosperous torments of the postwar world. *Blackboard Jungle* used the more typical yet no less powerful scenario of an inspiring teacher gaining authority over his unruly charges, and introduced an altogether new phenomenon of the adolescent experience, rock-and-roll music.

Issues beyond delinquency became the focus of other adolescent depictions, such as the sexual tensions that characterized *The Unguarded Moment* (1956), in which a high school student lusts after his teacher, and *Tea and Sympathy* (1956), one of the first teen films to deal, albeit implicitly, with the subject of adolescent homosexuality. Meanwhile, more distinct subgenres of teen films were forming. Beach movies became popular after the release of *Gidget* (1959) and *Where the Boys Are* (1960) and attained their greatest popularity with a series of films starring Frankie Avalon and Annette Funicello, beginning with *Beach Party* (1963). The adolescent horror tale genre also took shape in *I Was a Teenage Werewolf* (1957), *Teenage Zombies* (1960), and *Teenage Strangler* (1964). Even melodrama became a popular form of teenage storytelling, with *Blue Denim* (1959) addressing the taboo yet not uncommon problem of teen pregnancy and *Splendor in the Grass* (1961) examining sexual repression. By the early 1960s, Hollywood was clearly telling society that adolescence was only occasionally filled with fun and frolic, as adolescent characters were more often confronting deeper internal anguish, family problems, and cultural intolerance.

Such strife continued for adolescents through many films over the next decade, as best evidenced by the fragile teenagers in *Last Summer* (1969) and *The Last Picture Show* (1971), and especially the victimized girls in *The Exorcist* (1973) and *Taxi Driver* (1976). This mature discourse carried well into other 1970s teen films that addressed such topics as the loss of virginity (*The Summer of '42,* 1971), homosexuality (*Ode to Billy Joe,* 1976), pregnancy and abortion (*Grease,* 1978), and even religious and class conflict (*Saturday Night Fever,* 1977). When *Rich Kids* appeared in 1979, its story of a young teenage boy and girl who react to their divorced parents by forming an adult sexual relationship of their own seemed relatively common for the time.

Then as the 1970s gave way to the 1980s, the teen film genre faced a paradox: It became more popular and more prolific than ever before, and yet this new growth was largely regressive in its address of adolescents themselves. As movie theaters were converted to multiplexes in retail centers, they drew young crowds who were treated to a wide menu of story options. Horror became one of the first noticeable subgenres of the teen film to re-emerge at this time, with its psychopaths killing off sexually active youth in tales like *Halloween* (1978), *Friday the 13th* (1980), *Slumber Party Massacre* (1982), and *A Nightmare on Elm Street* (1984), films that were moral parables about the dangers of teenage transgressions. Films about adolescents using science also become popular for a short time, as teenagers were gaining competence with computers and video games. These characters were almost exclusively male and usually quite smart, although adult authority tended to suppress their potential, as seen in *WarGames* (1983), *The Last Starfighter* (1984), *My Science Project* (1985), *Real Genius* (1985), and *The Manhattan Project* (1986).

By far the most visible and most discussed of the 1980s teen subgenres was the sex comedy, which depicted sexually active adolescents in a reactionary mode that countered the Reagan era's moral conservatism. The majority of these films were nonetheless decidedly negative in their portrayals, demonstrating the complications of sex as well as its disappointments, confusions, and potential dangers. This was certainly the case in *Little Darlings* (1980), in which a girl quickly regrets losing her virginity, *Fast Times at Ridgemont High* (1982), in which a girl has an

abortion after two embarrassing sexual encounters, and *Risky Business* (1983), in which a boy enlists the services of a prostitute and watches his life fall apart thereafter. Indeed, sex may have been fun for some adolescents in these films, but it carried serious consequences, and by the mid-1980s, under the threat of AIDS and a rise in teenage pregnancies, movies could no longer make light of adolescent sexual experience.

The mid-1980s films of John Hughes also took the adolescent experience rather seriously, yet lacked the sexually explicit content, and came to represent the classic white, middle-class experience of youth during the decade. Starting with *Sixteen Candles* (1984), Hughes wrote and/or directed teenage characters as substantive, sincere, and shrewd, a winning formula that gave adolescents of the era a welcome portrait of themselves and their cohort. He followed with *The Breakfast Club* (1985), *Weird Science* (1985), *Ferris Bueller's Day Off* (1986), *Pretty in Pink* (1986), and *Some Kind of Wonderful* (1987), films representing a relatively wide variety of adolescent experiences, from dating, family, and school to issues of sex, class, and education.

By the late 1980s, the boom in the teen genre had slowed, with many movies then gaining popularity through home video rather than at the box office. Still, film depictions of adolescents had again taken on a more mature quality relative to the decade's earlier sex sprees and horror fests. Movies like *River's Edge* (1987) examined adolescent anomie in gripping detail; *Heathers* (1989) satirized the notion of high school popularity using murder and suicide; *Pump Up the Volume* (1990) revealed high school as a force that actually disenfranchises young people.

Thus, in the early 1990s the teen genre seemed well due for another serious engagement with social issues. Films like *Boyz N the Hood* (1991) and *Straight Out of Brooklyn* (1991) depicted young African American characters fighting for their lives in crime-ridden urban milieus under the hegemony of a racist legal and political system and under difficult family and social conditions. Films that followed in this vein also addressed race, youth, and delinquency, such as *Juice* (1992), *Menace II Society* (1993), *Above the Rim* (1994), *Fresh* (1994), *New Jersey Drive* (1995), and *Clockers* (1995). As with other genre cycles, though, the topic faded from films after a few years, and the film industry once again grew disinterested in exploring the lives and cultures of African American youth.

Subsequently, teen films in general developed a new comfort with crucial adolescent issues, looking at sexual orientation (*The Incredibly True Adventure of Two Girls in Love,* 1994; *Edge of Seventeen,* 1999), gender oppression (*Girls Town,* 1996; *Boys Don't Cry,* 1999), and the postmodern nature of teen films in general (*Scream,* 1996; *Not Another Teen Movie,* 2001). In the surest sign of change since the 1980s, teens on screen began having sex again, learning to explore their sexual practices and endeavoring actually to enjoy the process, as in an unlikely trio of films from 1999: *Cruel Intentions, American Pie,* and *Coming Soon.*

Curiously, the one topic that became the most sensitive—and then essentially forbidden—was juvenile delinquency. The dominant issue of teen films since the 1950s, from the mid-1990s onward delinquency became increasingly difficult to address, primarily due to the real-life violence of numerous school shootings by students. After the Columbine killings in 1999, very few teen films dealing with delinquency were released, and fewer still became hits; this was especially true of those dealing with violence, such as *Light It Up* (1999), *O* (2001), and *Elephant* (2003).

To their credit, many teen films of recent years have taken on other issues important to adolescents, such as family conflict (*The Virgin Suicides,* 2000), homophobia (*But I'm a Cheerleader,* 2000), pedophilia (*L.I.E.,* 2001), mental illness (*Donnie Darko,* 2001), body image (*Real Women Have Curves,* 2002), drug abuse and self-mutilation (*Thirteen,* 2003), and religion (*Saved!* 2004). These films continue the depiction of youth growing into increasingly savvy and self-aware young people. To their discredit, some teen films of the current era still actively exploit teenage fears and fascinations for profit: *Kids* (1995), *Wild Things* (1997), *Bully* (2001), *Swimfan* (2002), *What a Girl Wants* (2003), *Lords of Dogtown* (2005). Such films still seem inevitable as long as the media industries encourage adolescents to enjoy their own exploitation. Fortunately, recent adolescent depictions are often more educational than exploitative.

ADULT MEDIATION OF ADVERTISING EFFECTS

Active mediation is the most direct means of intervention among the four ways in which scholars commonly believe that parents and significant others influence the uses and effects of media among children and adolescents. The other methods are behavioral modeling, general communication norms, and rule making.

Scholars consider mediation of advertising an especially important form of parental influence, theorizing that the media serve as a bridge from the home to the larger society. Without parental guidance, persuasive media messages can become a child's most authoritative source of information. This occurs because children tend to believe that the media exist to entertain them, educate them, and tell them the truth—even though most media exist to make a profit, sell products, and advocate ideas. In addition, adolescents use media heavily as credible, appealing referents to guide them through the process of developing their identities and independence.

Scholars study mediation under the assumption that it should provide a particularly powerful counterweight to such media influences as advertising, but most studies have found relatively modest relationships between mediation frequency and such outcomes as children's interpretations of media content. This could be because operationalizations of mediation often have not seemed powerful enough to tap into the mechanisms of influence, partly due to their generality. Studies that gather more specific measures of parent-child discussion tend to find larger effects. Some scholars also have suggested that modest findings may indicate that most discussion of media is haphazard rather than purposeful. In addition, researchers continue to wrestle with the advantages and disadvantages of measuring mediation behavior from a parent's or child's point of view, which often differ.

To the extent that parents discuss advertising critically by analyzing its realism (including accuracy and truthfulness), values, and relevance, they can enhance children's skepticism of persuasive messages. They also can increase children's understanding of more truthful and useful content. This contributes to the child's functional communication competence—the ability to use communication resources, such as the media, strategically. Although adolescents rely on parents less than children do as sources of information and reinforcement, studies have shown that parents can continue to provide an important balancing influence to the media for them.

Currently, two approaches dominate the conceptualization of mediation. One, developed by Valkenburg and colleagues, considers rule-making behavior, which is relatively scarce, as a type of mediation, calling it *restrictive mediation*. It then combines reinforcement and counter-reinforcement of messages in a single construct, *instructive mediation*, which closely parallels a general measure of mediation developed by Austin known as *active mediation* and the construct *evaluative guidance* developed by Bybee, Robinson, and Turow. Valkenburg and colleagues also include *social coviewing* as a form of mediation, composed of coviewing behaviors, motivations and affirmative communication.

Another approach developed by Austin and colleagues breaks Austin's original active mediation construct into two types to help explain seemingly anomalous findings in which parental mediation has predicted undesirable outcomes. This approach distinguishes between *positive mediation* (affirmative comments that reinforce content as realistic, representative, enjoyable, relevant, and morally correct) and *negative mediation* (comments that question the content's

realism, truthfulness, accuracy, representativeness, relevance, or moral correctness). Research has indicated that mediation without any valence can be misinterpreted or can backfire.

Austin asserts that scholars should examine coviewing and rule making as conceptually distinct from mediation. According to this view, coviewing without discussion does not mediate anything, because it is a passive activity. Studies have shown that children often interpret coviewing of advertising as endorsement of the messages. In addition, because parents often use rule making to avoid discussion of content, rule making can represent avoidance rather than true mediation, and many children circumvent house rules by using forbidden material at friends' houses. When these children see persuasive messages, they will be less prepared to evaluate them critically. Indeed, some researchers have found that more rule making associates with less comprehension of advertising. What matters more than rules, some scholars suggest, is how rules are made, which reflects general communication norms.

Some inconsistencies exist in the literature regarding demographic correlates of mediation, but they tend to explain little regarding mediation patterns. Instead, parents' general communication styles and specific concerns about media tend to predict their mediation patterns. Research using Austin and colleagues' conceptualization has found that parents may use positive or negative mediation or a combination of the two mediation styles. Parents tend to employ negative mediation when concerned about media influence or skeptical of media messages. Parents tend to use positive mediation and social coviewing when they have a low level of skepticism and positive attitudes toward television in general. Positive mediators watch more television and more often watch together with the children. Negative mediators tend to watch less television and exhibit more skepticism, with much negative mediation occurring when the television is off. In some cases, positive mediation seems to occur out of a concern that condemning or countering messages might threaten family harmony. Fujioka and Austin found that the extent to which parents emphasize conformity and harmony in the household associates with positive mediation, whereas the extent to which parents welcome controversy and open discussion correlates with both negative and positive mediation.

Negative mediation seems to have protective effects with relevance to advertising, with or without demographic characteristics controlled. Although parents can use positive mediation selectively, and negative mediators often use positive mediation as well, research suggests that positive mediation can be counterproductive. In a study with third, sixth, and ninth graders, for example, positive mediation predicted higher expectancies for alcohol use, a greater desire to emulate characters in alcohol ads, and a stronger belief in the realism of the advertising. Negative mediation, on the other hand, predicted lower levels of expectancies for alcohol use. Positive mediation also has been shown to associate with higher levels of advertising desirability and expectancies for alcohol, even among college students, for whom parental influence presumably has waned. Some studies have found that negative mediation helps to activate skepticism toward advertising when critical-viewing skills are present but dormant. It also associates with fewer purchase requests, less materialism, and less parent-child conflict over potential purchases.

Scholars continue to work to clarify and strengthen conceptualizations and operationalizations of parental mediation. In addition, research is exploring the implications of mediation by peers. Some projects are applying the principles of mediation to studies of media literacy education in which influencers are adults or peers. This body of work suggests that discussion-based interventions can dampen the persuasive effects of advertising while enhancing the usefulness of educational content.

ADULT MEDIATION STRATEGIES

The word *mediate* means to intervene between two parties. To mediate children's media use, then, requires adults to intervene between children and media messages. The idea that there are mediation strategies implies that mediation is an intentional act. The three goals of adult mediation are to prevent negative media effects, to enhance positive effects, and to make children more critical media users. However, adult mediation of the way children interpret media messages is not always intentional. Children frequently see others' incidental comments and actions toward media.

Intentional or not, research has documented three basic types of adult mediation. The first is *restrictive mediation,* defined as parents' rules that seek to control the amount of media use (e.g., restricting TV to one hour per day), types of media content used (e.g., no violent shows), or the viewing environment, including where and when media can be used (e.g., restricting Internet surfing to a public room in the house). The notion refers to formally stated rules that are consistently enforced, but there is some difference in perspective here. Although many parents believe that they consistently restrict their children's media use, young children seldom report this to be so. Unless parents say that they are making a rule and explicitly enforce it, young children may not recognize their parents' mediation efforts.

The second type of mediation is called *coviewing*—use of media by adults and children together. Obviously, this strategy was identified in research on television viewing, but it can be applied to any medium. There is some disagreement, though, as to whether coviewing constitutes intentional mediation. Some have argued that most parent-child coviewing is coincidental; the parent happens to be watching a program, and the child chooses to view too. Others suggest that this act implies that the parent approves of the child's viewing the program. Hence, adults need not say anything during the show to influence children's interpretation of its message.

A third type of mediation is called *instructive mediation,* or talk about media content. Many have used the word *instructive* to refer to purposeful comments directed to children. An example might be a parent who sees a supermodel on television and says, "I don't know anyone who looks that thin. That's not how real women look." Many believe, though, that parents' inadvertent comments during viewing (such as a skeptical "hmph" during a commercial) also constitute instructive mediation. It is important to note that these comments can be positive (such as an adult's admiring comments about a celebrity) as well. If one intends to influence children's interpretation of media content, there is limited evidence that it is more effective to use statements with younger children ("That person is being very selfish.") and questions with older children ("Why do you think that person did that?").

Of the three strategies, parents report using restrictive mediation most frequently. Most national surveys by private foundations (such as the Kaiser Family Foundation or the Annenberg Public Policy Center) show that about three fourths of parents say that they consistently use restrictive mediation. Coviewing is usually reported as the second most used strategy, though most television coviewing only occurs during evening hours when parents watch shows they enjoy. Most studies that investigate instructive mediation ask parents how frequently they engage in various intentional discussions of media content. However, when

answering such questions, parents may not be thinking about the passing comments they make. It is hard to gauge how much more instructive mediation this adds to the mix, particularly if children do not pay attention to such comments.

Several factors influence how often adults use each of these strategies. One of the strongest influences seems to be parents' existing attitudes toward media's potential effects on children. Those with strong beliefs that television can lead to bad attitudes and behaviors in children are more likely to mediate, particularly with restrictive strategies. A second factor is the degree to which parents are involved in children's lives, especially in school or recreational activities or work around the house. In general, factors that limit parents' time with children (including their jobs or household work) also limit the time they can spend mediating children's interpretations of media content. A limited number of demographic factors also seem to distinguish parents who mediate more frequently and less frequently. Parents of young children, for example, mediate children's television viewing more than parents of older children. A greater number of educated parents have more often reported using instructive mediation. Differences in mediation of boys' and girls' media use, however, have not been consistent across these studies.

One interesting question that remains to be answered is how the use of media ratings systems and Internet filtering devices will fit into the mediation mix. The initial research on television ratings, conducted since 1999, seems to indicate that parents use the television ratings system as a rule to restrict viewing. To date, though, ratings systems have been used mostly by parents who already restrict content access, thus confirming already-established rules. Few parents who are low mediators have been encouraged to be so by media ratings labels. Adults' use of Internet filtering devices (such as filtering software or Internet browser settings) is not extensive enough as yet to show any sort of patterns. It could be that such devices mediate children's media use without any parent-child interaction. Alternatively, some parents may use these devices to initiate conversations when Web content is blocked from a child's view.

ADULT MEDIATION OF VIOLENCE EFFECTS

Adult mediation of violence effects refers to the behaviors that adults—usually parents or teachers—engage in to prevent children from experiencing harmful effects from exposure to media violence. Adults can mediate any form of violent media; however, the majority of the research has been done on mediation of violent television. Adult mediation can take several different forms. Each form of mediation has been met with varying effectiveness.

Research shows that the most successful form of adult mediation occurs when adults talk with children about violent television. This form of adult-child communication is often referred to as *active mediation*, although several other labels are commonly used as well. Active mediation can occur at any time; however, we know the most about active mediation that occurs while both the adult and the child are consuming violent media together.

Adults can make a variety of comments when using active mediation. For example, they might explain to a child that a violent program is not real or that the violent characters are not nice. Or adults might encourage the child to think about the negative consequences of violence or aggression. In addition, adults might talk to a child about the special effects that are used to create the violent scenes.

Active mediation of violent media has been linked with many positive outcomes among children. For example, children whose parents talk with them about television violence often are more critical viewers of

television than other children are. These children typically have more negative attitudes toward television violence, like violent characters less, and are less aggressive than children whose parents engage in less active mediation. It seems that consistent exposure to active mediation of television violence socializes children into a generally negative orientation toward violent material.

The effectiveness of active mediation can depend on the age of the child who receives the messages. For instance, making strong statements that communicate the parents' negative evaluation of the program and the characters (e.g., "I don't like how this character tries to solve problems") is particularly effective among young children (usually younger than about 9 years old). However, as children become older, they may resent hearing this kind of lecture and become less receptive to these messages. On the other hand, older children (usually older than age 9) benefit when adults ask questions that help them come to their own conclusions about the violent program (e.g., "Do you think that person would have many friends in the real world?"). As a result, messages should be tailored to the unique needs of the children who receive them.

The parents who are most likely to use active mediation are educated and believe that television can have a negative effect on their children. In addition, parents are more likely to use active mediation with younger children. Overall, however, few parents use active mediation. Some work suggests that parents do not believe that active mediation is an effective way to prevent their children from experiencing harmful media effects.

Another form of adult mediation is called *restrictive mediation*. Restrictive mediation refers to the rules and regulations that parents set for their children's viewing of media. Parents might have rules about how much television their children can view, how long they can view it, or what kinds of programs or channels are unacceptable. Parents can vary in terms of whether they have rules as well as how strictly they enforce their rules.

Restrictive mediation also is linked with some positive outcomes among children. Children whose parents restrict their television viewing are usually less aggressive than other youngsters. In addition, when these children do view television, they tend to be critical viewers.

However, some work suggests that restrictive mediation can backfire. That is, the children of parents who are very strict sometimes rebel against the rules. These children actively seek out the restricted content (e.g., at a friend's house) and are more aggressive than children whose parents have set more moderate rules. This tendency toward rebellion becomes particularly likely as children get older and reach adolescence.

Restrictive mediation is used with more frequency than active mediation is. Parents often feel that it is easier to set and enforce rules than to talk to their children about television. In addition, parents often believe that restrictive mediation will be more effective than active mediation. Restrictive mediation is most likely to be used with younger children.

A third form of adult mediation is called *coviewing*. Coviewing refers to parents viewing violent television with their children. Although parents sometimes talk to their children about television while coviewing, this term refers to the simple act of parents and children sharing television together without any formal discussion of the content.

Although coviewing can have positive effects when educational television is shared, its effects tend to be negative when violent television is coviewed. For example, when parents coview a violent television program with their children—and do not say anything to contradict what is shown—children interpret their parents' presence as an endorsement of the material. Children tend to pay more attention to the content that is coviewed, they become more involved in it, and they are more vulnerable to being affected by it. As a result, coviewing of violent television is often linked with increased aggression among children.

Coviewing is another commonly used form of adult mediation with both younger and older children. Coviewing of violent television often occurs when parents and children share viewing interests. In other words, parents often coview violent television because they like the programs. Not surprisingly, parents who coview usually have positive attitudes toward television.

ADVERTISING, BODY IMAGE AND

Cumulative exposure to thin-ideal images in advertising and other forms of mass media is of greatest concern with regard to the development of positive or negative body image in women and men and boys and girls. The review of research in this area suggests a positive relationship between thin-ideal media exposure, thin-ideal advertising, and body image disturbance in young women and girls, particularly among whites. Body image disturbances are also increasing among boys, who have an increasing awareness of body image as a result of advertising featuring a muscular ideal.

THE THIN IDEAL IN ADVERTISING

Health communication and social science scholars suggest that the body shape standard for women as represented in mediated images has become increasingly smaller over the last several decades. We see these portrayals in entertainment programming on prime-time channels and cable, in music videos, in the editorial content of women's magazines, and in all forms of advertising. The Social Issues Research Centre reports that young women now see more images of what are considered to be outstandingly beautiful women in a single day than their mothers saw throughout their entire growing-up years. Some researchers argue that chronic dieting is a direct result of the social pressure on American women to be unnaturally thin, and they argue that this body shape ideal is a result of media exposure to images depicting and promoting images of thin women, especially in advertising.

Scholars studying the social effects of such media as advertising argue that, through repeated viewing of these images, women and girls are taught to judge and compare their own body shapes and sizes. Even though the advertising industry has received a good deal of criticism for its use of ultra-thin models, the industry seems to be reluctant to modify its practices because, in the end, images of thinner women sell.

EFFECTS OF EXPOSURE TO THIN-IDEAL IMAGES IN ADVERTISING

Because many researchers suggest that editorial content nowadays is so similar to advertising content, it has become even more difficult for readers and viewers to distinguish between the two. This is especially relevant for younger girls who read teen magazines and may not be very knowledgeable about the influences of advertising. Jean Kilbourne argues that advertising is a highly persuasive and pervasive medium that permeates society and sends subtle and repeated messages promoting the thin ideal. She further argues that it is the cumulative exposure to ads that is most harmful to women and girls. Other scholars suggest that advertising has been accused of unintentionally making women feel self-conscious and inadequate because advertising may play a role in reinforcing a preoccupation with physical attractiveness.

Several studies have examined predictive factors of body dissatisfaction, drive for thinness, anorexia, and bulimia—all correlates of body image disturbance—and have examined the relationship of media use and exposure as positive correlates to these dependent variables. These studies have been conducted via surveys and experiments with younger girls, teenage girls, college-aged women, and women older than college age, and most have been conducted to gauge the short-term psychological effects of exposure. Overall, experimental research finds that short-term exposure to thin-ideal images is a significant predictor of body dissatisfaction in college-aged women and high school girls. Yet the general conclusion from studies of this nature is that the key to better understanding the degree of effect on women and girls' body self-esteem and body image lies in a better understanding of media exposure patterns, especially long-term exposure to specific types of content.

Research on the social effects of mass media with respect to body image distortion in women and girls emphasizes that it is the internalization of the thin-ideal beauty standard that is a causal factor in negative body image and disordered eating in women and girls. It is also suggested that the internalization of this ideal comes from comparisons between oneself and target others as represented in the media via social comparison. Some studies have found that women and girls want to be thin because thinness is associated with beauty and attractiveness, whereas other studies have found women's desire to be thin to be associated with other positive characteristics, such as popularity, improved performance in school or on the job, and attractiveness to the opposite sex. Overall, research findings in mass communication and social and clinical psychology point to a causal link between exposure to thin-ideal media content and body image disturbance in populations of varying ages. For example, in a 1993 study that tested a sample of 8-to-14-year-old girls, Mary Martin and Patricia Kennedy found that girls who reported reading fashion magazines and who viewed models in advertisements and fashion layouts were more likely to feel badly about their own appearance than those who did not view similar content. In parallel studies with college-aged women, Kathy Wilcox and James D. Laird found that women who viewed images of slender models in magazine advertisements and compared themselves to the media models were more likely to report decreases in weight satisfaction and general body self-esteem.

The negative effect of mediated body image ideals is not exclusive to women and girls. Research from Anorexia Nervosa and Related Eating Disorders, Inc. (ANRED) suggests that the number of men and boys struggling with diagnosed eating disorders is on the rise. ANRED research reports indicate that approximately 10% of the male population in North America is affected by an eating disorder. More startling are the reports suggesting that men and young boys are engaging in excessive weight training in conjunction with the consumption of protein drinks that promise to provide the ideal muscular body type. According to a Harvard study on muscle dysmorphia, as many as 3 million males in the United States use anabolic steroids to increase muscle mass.

Chris Cobb argues that young and adult men have an increasing awareness of their body image because they are pummeled with hypermasculine images and images in lifestyle and fitness magazines that make them feel inadequate because they are not as muscular as the models in the ads. Cobb further reports that role models for young boys—male action figurines such as GI Joe—have increased in chest and bicep size over the last three decades. Consequently, young and adult men are motivated to engage in dangerous behavior to change their body shapes and sizes. Overall, research studying the relationship of media exposure to body dysmorphic disorder with men and boys suggests that exposure to ideal image advertisements is linked to changes in mood and in overall self-evaluations. In some cases, exposure is also linked to higher levels of depression and significantly higher levels of muscle dissatisfaction. For example, Harrison G. Pope, Jr., Roberto Olivardia, Amanda J. Gruber, and John J. Borowiecki report that men have increased their efforts to stay lean while still building muscle mass because of real-ideal discrepancies found in media content.

Communication scholars studying the potential effects of thin-ideal media exposure argue that the viewing of the thin beauty ideal or the muscular ideal in television commercials will likely result in a negative effect on body image of boys and girls because the viewing of the commercials will activate a self-schema that reminds the individual about the importance of appearance. An individual's concern with appearance, combined with a lack of understanding in the processing of visuals, makes for a harmful combination when young girls and boys are faced with unrealistic images of body shape and size. Visual communication scholar Paul Messaris argues that visual literacy is a prerequisite for the proper comprehension of visual media. According to Messaris, the allure and appeal of visual media make it very easy for a viewer to be duped by single or multiple images, such as images in advertising, if that viewer has little understanding of the ways visual media can misinform, distort, and manipulate. Jean Kilbourne further suggests that the processing of advertising images can be unconscious, and even though particular information might help viewers understand that the image being viewed is not real, the comparison between oneself and an idealized media model still seems to take place.

However, with the imagery in advertising becoming more tantalizing and sexy, and with an increased emphasis on beauty and thinness in media targeting adolescent girls and women, the problem is projected only to increase.

ADVERTISING, DECEPTIVE PRACTICES IN

Deceptive advertising practices are those that are likely to mislead the consumer through false claims, misleading information, or inadequate disclosures. Although children have the potential to make and influence purchases, they lack developmental skills to fully comprehend and appreciate advertising practices. As a result, they may be misled by advertising practices that do not take into account their limited competencies. Research has examined the nature of various deceptive practices, and self-regulatory and public policies have been developed to redress these practices.

PUBLIC POLICY AND THE FEDERAL COMMUNICATION COMMISSION (FCC)

Acting in its role as trustee of the public interest, the Federal Communication Commission (FCC) has established public policy regarding children's advertising. These policies regulate advertising during children's programs in two areas: (1) limiting the amount of time allowed for advertising during children's programs, and (2) creating a *clear separation* between advertising content and programming content. This clear separation principle attempts to address the limited abilities of children to distinguish program from commercial content and encompasses three areas of potentially deceptive practice: separators or bumpers, host selling, and program-length commercials.

Separators or Bumpers

One component of the clear separation principle is the use of short video segments shown before and after commercial breaks to indicate a change between program content and commercial content. Known as *bumpers* in the industry, these short segments usually include such phrasing as "We'll be right back!" Research on the effectiveness of this practice is very limited. The two studies that have been done (in the late 1970s) indicate that the use of bumpers does not appear to be effective for children under the age of 7. Response time to recognize a commercial may be closer tied to children's ability to distinguish an ad from a program rather than to the bumper signaling a change.

Host Selling

A second component involves the potentially deceptive practice of using children's program characters to promote products either during the program or in commercial blocks adjacent to the program. Research indicates that, although this practice was

prevalent in the early 1950s, it declined over the next 10 years and was banned by the FCC in the 1970s.

Program-Length Commercials

Originally conceived as a program with the principal purpose of promoting products (particularly toys) to children, this content has changed to more closely resemble that of host selling. Research suggests that toy-based programming began in the 1980s with arrangements between toy companies and television producers to develop programming content that would promote toys and ancillary products, such as *Strawberry Shortcake* and *He-Man and the Masters of the Universe.* Since the passage of the Children's Television Act in 1990, the FCC has defined the program-length commercial as a commercial promoting a product that is also connected to the main program content. For example, showing a traditional commercial promoting Dora's playhouse during an episode of *Dora the Explorer* would be considered a violation of the new definition of a program-length commercial.

SELF-REGULATION AND THE CHILDREN'S ADVERTISING REVIEW UNIT (CARU)

In 1974, in response to concerns about children and advertising, the advertising industry created a self-regulatory program, the Children's Advertising Review Unit (CARU), to monitor deceptive practices and provide guidelines for responsible advertising to children under the age of 12. These guidelines encourage advertisers to take into consideration the development of the child in order to provide appropriate information and avoid misleading the child. Among numerous suggestions, the guidelines offer procedures for providing disclaimers and disclosures and for use of premiums.

Disclaimers and Disclosures

Disclaimers reveal information about a product to avoid misleading the consumer. Those most common in children's advertising include such phrasing as "batteries not included" or "items sold separately." Research suggests that, although product disclaimers in children's advertising have become more prevalent since the 1950s, the language used since the early 1990s is adult directed. This is particularly relevant, as the few studies that have explored the effects of disclaimers with young children (8 years old and younger) indicate that children often do not understand the disclaimer and show greater comprehension of the intent of the disclaimer when simpler language is used. For example, research suggests that children are more likely to understand that a toy needs to be assembled before playing with it when the disclaimer uses simpler terms, such as "you must put this together" rather than "partial assembly required." These findings suggest that disclaimers need to address their audience's developmental level to be most effective with the target audience.

Premiums

Premiums are prizes that are often included with a target product to encourage the consumer to purchase it. For example, a cereal that offers a Star Wars spoon inside the box entices the consumer to purchase the cereal to obtain the prized spoon. Premiums have been used in a small portion of advertising aimed at children, but they are most likely to appear in ads for fast-food restaurants. A few studies have examined the impact of premiums on purchasing behavior. Research indicates that many mothers feel that premiums are overemphasized in commercials, yet observations of families in the supermarket indicate that very few children actually mention the prize as a reason to make a cereal purchase. One study suggests that children who did ask for a product because of the premium were more likely to get the product than those who did not ask for the premium. This is further supported by another study in which mothers indicate that requests for premiums are a strong motivation for them to purchase products for their children.

A combination of self-regulatory programs and public policies help guide advertisers from engaging in deceptive advertising practices. Yet little current research has been conducted regarding misleading strategies employed in contemporary society.

ADVERTISING, EFFECTS ON ADOLESCENTS

Advertising is pervasive in our society, and the American Academy of Pediatrics estimates that the typical child in the United States sees almost 40,000 commercial messages each year. Young people are an attractive market for advertising. Not only do they have disposable income for personal purchases, but adolescence is the life stage during which brand preferences are formed. The manifest intent of advertising is to increase brand awareness and purchase, but advertisements can have unintended effects on adolescent health. This entry examines the possible impact of advertising on eating disorders, alcohol consumption, and smoking.

Adolescence is a period of change marked by tension between childhood and adulthood. Adolescents begin to experiment with adult roles as they become increasingly oriented toward relationships with their peer groups. These new roles are accompanied by uncertainty. Because media content is attractive and easily available, adolescents may turn to the mass media for information about these new roles. The pervasiveness of advertising, along with evidence that adolescents are more susceptible to its influence, gives rise to concern that it might become a source of information about adulthood that can lead to unhealthy behaviors.

BODY IMAGE AND EATING DISORDERS

Adolescence brings concerns about media's impact on eating disorders. The widespread incidence of anorexia (eating too little) and bulimia (inducing vomiting after overeating) has led scholars to examine media messages about body images. In American culture, physical attractiveness is linked to thinness. Analyses of *Playboy* centerfolds, female characters on television, women in magazine ads, and even Miss America contestants indicate that the ideal female form has become slimmer over the years. The increase in women's fitness magazines, the number of magazine articles about dieting and weight loss issues, and the number of advertisements for diet products illustrate further reinforcement of the thin ideal.

There are several explanations why advertisements and other media content are expected to influence adolescents' body image. Albert Bandura's social learning theory holds that attractive and rewarded characters are more likely to be modeled. So, adolescents are likely to try to look like the thin characters they see in the media. Leon Festinger's social comparison theory contends that people compare themselves to others they believe represent ideal or reasonable models. So, attraction to slim media characters and celebrities can be linked to body dissatisfaction, the drive for thinness, and symptoms of disordered eating.

Adolescent girls are believed to be especially susceptible to media influence on disordered eating. During puberty, estrogen causes adolescent girls to acquire more fat, especially in the breasts and hips. Adolescence is also a time when girls tend to view their bodies critically and begin to feel negatively about their physical appearance.

Researchers have found some connections between media use and disordered eating. Symptoms of eating disorders have been linked most consistently to thin female magazine models and fitness magazine reading. These effects are not direct, however—that is, scholars have not found that exposure to these models translates directly into eating disorders. Instead, exposure is linked to dissatisfaction with one's body, the drive to be thin, and various eating disorder symptomatology. Self-esteem appears to affect the relationship between exposure to thinness-promoting media content and development of eating disorders. Adolescent girls with lower self-esteem are more likely to be dissatisfied with their bodies and more likely to compare themselves with media images.

Most research on media and eating disorders has focused on female adolescents, but awareness is growing that media images can affect males. Unlike females, who want to be thinner, male adolescents want to be more muscular. There is evidence that the muscular male has become society's ideal; men's health and fitness magazines focus on models who are muscular and have low body weight and fat. Exposure to these images have been linked to male body dissatisfaction.

DRINKING

The American Pediatric Association points out that underage drinking is an important health risk for adolescents. Between 2000 and 2002, more than 17,000 adolescents died in alcohol-related automobile accidents. Alcohol increases the risk of adolescent suicide and homicide.

Alcoholic beverages are the most common type of drink on television and the most commonly advertised beverage on sports television. Scholars estimate that children will see more than a million acts of drinking on television by the time they are 18. Drinkers are portrayed as wealthy, successful, and attractive; advertisements associate alcohol with sex and romance, athletic ability, popularity, and camaraderie. Negative consequences of overconsumption are rarely seen.

The pervasiveness and glamour of these images of alcohol stimulate concerns about underage drinking and alcohol abuse. Bandura's social learning theory suggests that these ads are likely to serve as models for the audience. There is indirect evidence that alcohol advertising might be linked to underage drinking. Adolescents are more likely to drink the more heavily advertised brands. Watching college basketball and football (which are heavily sponsored by brewing companies) is associated with alcohol use in adolescents.

The strongest effects of alcohol advertising may be the fostering of positive attitudes toward alcohol and drinking. Budweiser's ad agencies have produced clever commercials that have created popular icons, such as the Budweiser frogs, annual events such as the "Bud Bowl," and catch phrases ("Whassup?"). The Clydesdale horses trot out holiday greetings each year. Ads such as these are rated among adolescents' favorites. Alcohol ads use techniques designed to attract adolescents' attention. Ads feature rock music, scantily dressed young women, and adolescent humor. Researchers observed that British adolescents became more aware of alcohol ads as they got older. Moreover, they reported that they liked the ads because they admired the lifestyles the ads depicted. Other researchers found that liking beer advertisements led to positive attitudes about beer and directly influenced beer consumption. Adolescents who enjoy advertisements are likely to drink earlier. Adolescents are likely to notice and like alcohol advertisements because they promote an attractive, adult lifestyle that adolescents find desirable and relevant to their needs to feel more adult. Thus, attention to alcohol advertising appears to stimulate a predisposition to drink.

SMOKING

It has been established that the use of tobacco contributes to the death of the user. An estimated 1,200 smokers die each day, and countless others try to quit the habit. Some believe that tobacco companies target adolescents to replace those lost customers. Scholars from the National Cancer Institute claim that tobacco companies intentionally market to youth in order to build new customers because they know that few people start smoking in adulthood. U.S. Department of Heath and Human Services statistics support the notion that smokers adopt the habit while they are young; 50% of smokers begin to smoke by age 13, and 90% begin by age 18. Between 1994 and 1998, the National Cancer Institute reported that 18% to 20% of all 12-to-20-year-olds smoked. Part of the explanation for adolescent smoking is misinformation about the nature of nicotine addiction. According to a 1994 surgeon general's report, young people believe that they can easily stop smoking, so they assume that the widely publicized health risks of smoking will not affect them.

Smoking is not typically seen on television. Tobacco ads were banned from broadcast media in 1971. Since then, smoking in television programs has also declined. Although most research on advertising effects on children focuses on television ads, smoking is one area where television has little influence. Television viewing declines, however, in adolescence. Young adults spend some of that time with magazines, which still carry tobacco ads. Magazines with large youth audiences have more tobacco advertising. In 2000, tobacco companies spent more than $100 million to advertise cigarettes in magazines that had significant youth readership. A study by Charles King and Michael Siegel found that, in 2000, tobacco ads in magazines reached 80% of all adolescents in the United States.

Academics, medical professionals, and public health officials are in general agreement that tobacco advertising has contributed to adolescent smoking. Some of the evidence is historical and correlational. Smoking among adolescent girls, for example, increased at the same time that advertising for women's brands increased. Adolescents' cigarette brand choices are concentrated in the most heavily advertised brands; brand choice and advertising seem to be more tightly connected for adolescents. Three years after the start of the Joe Camel advertising campaign that appealed to youth, Camel increased its share of the adolescent smoking market from .5% to 13%.

Although it is difficult to prove that tobacco advertising causes adolescents to smoke, scholars offer several explanations for its impact. Adolescents are particularly susceptible to peer pressure, and tobacco advertising suggests that smoking is common. Tobacco ads that depict smokers as physically active and energetic undercut awareness of the health risks associated with smoking. Tobacco advertisements use appeals that are attractive to the young. Smokers are presented as youthful, attractive, popular, and adventurous; tobacco is presented as smelling good and tasting good.

A longitudinal study of Massachusetts youth followed a group of adolescents from 1993 to 2000. Because the youth were followed over a period of years, the researchers were able to examine the forces that lead nonsmokers to become smokers. Smoking was affected by some social factors, such as having friends and adult family members who smoked. Smoking was also predicted by awareness of advertising slogans and brands. More interesting, however, is the connection between awareness of advertising and the belief that smoking had social value (e.g., increased attractiveness, maturity, popularity, and independence). The researchers concluded that tobacco advertising leads to adolescent smoking because it increases smoking's social value for adolescents.

CONCLUSION

In summary, it is important to remember that advertising is not the only source of potentially harmful effects for adolescents. Thin body ideals, alcohol use, smoking, and stereotypical images are commonly found in television programs, movies, and music videos and as themes in popular music. Even though there are few instances of smoking on television, characters rarely refuse to smoke or make disparaging comments about smoking or smokers. Smoking in the movies is more common than in real life. Even G-rated films commonly contain smoking and drinking; some animated children's films feature smoking. The mass media present many unhealthy messages to children and adolescents.

ADVERTISING, EFFECTS ON CHILDREN

Children are inundated with marketing messages for toys, fast foods, cereals, snacks, electronics, and media content itself. Historically, concerns about advertising to children surround the issue of fairness. Is it fair to target children who are unable to distinguish commercial from noncommercial content or unable to recognize that the goal of the advertisement is to persuade them to buy a product? Moreover, there are concerns about the effects of marketing messages on children's attitudes (e.g., materialism), childhood obesity, and parent-child conflict. This entry examines the research evidence related to children's perceptions of advertisements and potential effects of these persuasive messages.

COGNITIVE ABILITIES NECESSARY TO PROCESS ADVERTISING

To respond to advertising in an adultlike manner or to defend against ads effectively, children must be able to distinguish programs (noncommercial content) from commercials and understand the persuasive intent of advertising. Research, conducted primarily with television, demonstrates that young children have difficulty doing both.

Children's Ability to Discriminate

Numerous studies have documented that children below age 5 have difficulty discriminating between television programs and commercials. When children do begin to discriminate, they often do so based on perceptual characteristics. For example, young children say that commercials are shorter than programs. They also frequently identify commercials as part of the program. In an experimental setting in which children were asked to retell the story of the program just viewed, Dale Kunkel found that most children wove the commercial scene into their sequence of story events even though they had been asked to tell only the story of the program.

Media policies and advertising practices have contributed to children's confusion and difficulty in discriminating between commercial and noncommercial content. In 1974, the Federal Communications Commission (FCC) created the *separation principle.* Separation devices (e.g., "We'll be right back after these messages") are segments roughly 5 seconds in length that are shown before and after commercial breaks. Rather than helping children understand the transition from program to commercial, research demonstrates that separators actually carry children's attention through the commercial to the next program segment because the separators include fun characters, music, and singing. Their form and style are very similar to those of the program itself.

Another advertising practice, *host selling*, makes discrimination difficult for children because the same characters used in commercials are featured in the adjacent program content (e.g., the Fruity Pebbles cereal ad is aired during a break in *The Flintstones* cartoon). Although host selling has been prohibited since 1974, evidence suggests that it is not effectively restricted. Kunkel's examination of the issue revealed that children aged 4 to 8 were less able to distinguish programs from commercials in host selling contexts.

Finally, the purpose of the *program-length commercial* is to expose children to a product line (e.g., GI Joe action figures) with the goal of increasing product sales and program popularity. The distinction between traditional, program-related product licensing and program-length commercials is based on which comes first, the program or the product. Historically, television programs were created to entertain or inform the viewing audience. Marketing of products then followed if the program was successful. In contrast, the program-length commercial was originally

conceived as a vehicle for promoting products to the child audience. Barbara Wilson and Audrey Weiss found that program-length commercials impaired discrimination judgments, and Patricia Greenfield and colleagues found they promoted imitation rather than imaginative play.

The Ability to Understand Persuasiveness

Children usually do not recognize the persuasive intent underlying advertising until around age 7 or 8. To process advertisements effectively, the viewer must recognize that the source of the advertisement has perspectives and interests other than those of the audience, that the source intends to persuade, and that biased messages demand interpretive strategies different from those required by unbiased messages. Young children, however, are very egocentric and lack these perspective-taking abilities; thus they are more vulnerable to misleading information.

Children often do not understand that claims may be exaggerated and that products are not as dazzling and exciting as they appear on television. The production techniques or formal features (e.g., audiovisual special effects, type of music, quick cuts) used in children's advertisements contribute to these perceptions. Special effects are largely holistic and designed to create moods, images, and impressions rather than to convey accurate information about products.

EFFECTS OF ADVERTISING MESSAGES

The intended effect, from an advertiser's perspective, is to generate requests for and consumption of products. Research indicates that advertisements are extremely successful at accomplishing this goal. Children remember products presented in advertisements, they develop loyalty and preferences for particular brands, and their desire for products is increased after exposure to advertising messages. Repeat exposures, premium offers, and favorite TV characters increase the likelihood that children will desire products and make purchase requests. Television viewing habits also seem to play an important role in advertising effects. Correlational data from multiple surveys indicate that heavy TV viewers want more advertised products and consume more advertised foods than light TV viewers. It is assumed that exposure to advertising messages produces these consumption behaviors, but it is likely that the reverse is also true. Children with an interest in particular products turn to television, magazines, the World Wide Web, and other sources to seek out information about products.

Although selling products is the desired outcome for advertisers, advertising messages have unintended consequences. Two are discussed here: eating habits and parent-child conflict. The issue currently in the forefront—from media coverage to policy efforts—surrounds the increase in childhood obesity. Analyses of television advertisements clearly indicate that approximately half of these ads are for unhealthy foods (sugared cereals, candy, snack foods, drinks, and fast foods.) As noted above, advertisements for food-related products do lead to increased desire for and consumption of these foods. However, Kunkel suggests that, to establish causal relationships between food marketing and health outcomes, more complicated models are needed that identify which variables contribute to an outcome like obesity. For instance, parents play an important role, as they are often the ones who purchase unhealthy foods at children's requests. This leads to a second indirect effect, parent-child conflict. Research conducted in the mid-to-late 1970s by Robertson, Atkin, and others found that parent-child conflicts transpired when parents refused to give in to children's requests. Children became disappointed, argued, and persisted in response to their parents' refusals. Such conflicts seem inevitable considering that advertising messages pervade our media landscape. New challenges, however, have emerged with digital marketing.

DIGITAL MARKETING STRATEGIES

In the 1996 report *Web of Deception,* Kathryn Montgomery and Shelly Pasnik documented potentially harmful online marketing and data collection practices directed toward children. Specifically, the report focused on invasion of children's privacy (solicitation of personal information) and manipulation with unfair advertising practices (creating product spokescharacters who develop relationships with children). In October 1998, Congress recognized the need to regulate online marketing to children and passed the Children's Online Privacy Protection Act (COPPA), which went into effect April 21, 2000. COPPA provides safeguards for children's privacy on the Internet by regulating the collection of personal

information from children under age 13. Despite this legislation, online advertisers continue to employ tactics that raise concern.

Montgomery describes three marketing strategies with problematic consequences: relational marketing, seamless integration of content and advertising, and branded environments. Relational or one-to-one marketing is defined as the development of unique, long-term relationships with individual customers to create personal sales appeals based on individual preferences and behaviors. Tempting online users with incentives, offering subscriptions to newsletters, or using cookies (small files created by a website server and stored on the user's computer) to enable companies to create profiles of individual users. Children are particularly vulnerable because they find offers of promotional material and free products in exchange for personal information very enticing. Content and advertising are seamless on the Web. There are no separation devices such as those as found in television, and the amount of time children spend exploring commercial websites is limited only by their own interest and parental regulation. Finally, the product itself (e.g., *Barbie, Hot Wheels*) is the content; hence, branded environments provide children with unfettered opportunities to interact with products and characters.

The literature surrounding children's perceptions of online advertising and potential effects is limited. As children navigate this seamless environment of entertainment and commercial content, what are their perceptions, and how might these online experiences influence consumer decisions? The research findings from television may or may not apply to online environments. One exploratory study, however, does provide food for thought. Lucy Henke explored children's perceptions of the persuasive intent of favorite websites. She asked children aged 9 to 11 years to complete questionnaires that assessed favorite after-school activities, followed by participation in a Web search session. Websites were bookmarked (i.e., *Toys R Us, Ben & Jerry's,* the Museum of Science, *Foster's Daily Democrat,* and *CNN*), and lists about other sites (e.g., *Batman Forever, ESPN,* and *MTV*) were provided to the children. When children were asked about their favorite sites, 74% named commercial websites as their favorites, but only 13% said that the purpose of their favorite site was to advertise. Interestingly, they thought the purpose of the site was for entertainment, which suggests that even children 9 to 11 years old may not be aware of the commercial intentions of many websites.

OTHER CONCERNS: MARKETING TO "UNDERAGE" YOUTH

In a report requested by President Clinton and Congress following the Columbine school shootings, the U.S. Federal Trade Commission (FTC) found that the motion picture, music recording, and interactive game industries had engaged in widespread marketing of violent movies, music, and games to children that was inconsistent with the cautionary messages of their own parental advisories. For instance, nearly all the video game companies reviewed (via internal marketing plans) marketed violent, M-rated games to youth under the age of 17.

In a follow-up report in 2004, the FTC found problematic practices in the retail industry and in cross-industry marketing. The commission conducted an undercover shopper survey in which children and teens (under age 17) attempted to purchase music with explicit-content labels, R-rated DVDs, and M-rated interactive games at retail outlets, including Target, K-Mart, Toys-R-Us, and Circuit City; retail salespersons sold music, DVDs, and games to 83%, 81%, and 69% of the "underage" shoppers seeking to buy them, respectively. The commission also noted several examples of cross-marketing of entertainment media products with different ratings, labels, and intended audiences. An example of this is placing a movie trailer for *The Matrix* movie (rated R) within a video game (rated T). The intended audiences for these media products are different, but the marketing message is strategically placed to expose a younger audience to potentially inappropriate entertainment content. The ultimate question is whether or not these cross-media strategies have the effect of attracting a younger child or teenage audience to entertainment media intended for older audiences.

CONCLUSIONS

The research literature surrounding the effects of advertising on children provides important insights about our youngest consumers. Children and adolescents now have significant personal resources that allow them to make individual consumer choices as well as affect purchasing decisions within the family.

Yet, there remain unanswered questions about how advertisements—whether on television, on the Web, or in school—actually influence children's perceptions about products, purchasing decisions, health outcomes, and negotiations with parents, to name a few. Researchers who elaborate on past efforts and approach children's advertising in innovative ways will advance our understanding related to effects of these persuasive messages.

ADVERTISING, ETHNICITY/RACE IN

Research on the impact of ethnicity and race in youth's experience of advertising focuses on the exposure of different racial and ethnic groups to advertising, the amount and nature of representation of various racial groups in advertising, and the effect of that content on viewers from diverse backgrounds. The findings suggest that there are racially specific patterns of participation and racially specific content in advertisements. Moreover, there is evidence that the content has differential effects on the diverse members of the viewing audience. Advertising affects attitudes toward the ads, the products, and the individuals portrayed.

EXPOSURE TO ADVERTISING

Youth may be exposed to advertising on television, DVDs and videotapes, radio, the Internet, and in magazines. It is estimated that children under 14 are exposed to at least 40,000 ads yearly, with African and Hispanic American youth having higher levels of exposure compared to European American youth. The potential power of these advertisements is great, as advertisers estimate that children are directly responsible for $24 billion in purchases and indirectly influence about $188 billion in family purchases.

REPRESENTATION OF RACE AND ETHNICITY IN ADVERTISING

Diverse ethnic and racial groups have distinct patterns of inclusion in advertising. Research conducted since 2000 indicates that European Americans are overrepresented in commercials in adult programming and that African, Asian, and Hispanic Americans are underrepresented. More ethnic and racial diversity exists in ads associated with media directed toward children, in which approximately 57% of the advertisements portray participants of diverse groups. In a study of commercials associated with children's programs, European Americans represented 75% of the characters, African Americans represented 20% of the characters, and Latina/o and Asian Americans each accounted for 2% of the characters. Regardless of the media type, Native Americans are virtually invisible in advertising, with participation in the range of

5 or 6 characters out of 3,300 in a sample of commercials in children's programming.

THE NATURE OF RACIAL AND ETHNIC PORTRAYALS IN ADVERTISING

Advertising presents diverse racial and ethnic groups in distinct and limited ways. European Americans are presented as powerful, knowledgeable initiators of action and problem solvers. They are more likely to be spokespeople, providing important information about products. Authority and high status are typically portrayed by European Americans, often in white-only commercials. European Americans are likely to be the only models in important toy ads. European Americans are not stereotyped as a racial group in advertising—they are seen in all types of commercials for all types of products, and they are presented in all types of settings and can appear as adults, teenagers, or children.

The picture is very different for other racial and ethnic groups. Members of these groups have more limited roles, are associated with a restricted number of products, and appear in only a limited number of settings. Since 2000, commercials for financial services and restaurants in adult programming have presented African Americans as attractive and respected adults. But in ads directed to children, African Americans are still more likely to appear as laborers or servicepeople, as entertainers associated with music, or as athletes. They are less likely to have high-status roles, and they do not typically sell personal care products. However, because of the popularity of African American celebrities, there are a few examples of all-black advertisements.

Hispanics have a very mixed presence in advertising. In commercials directed to children, Hispanics are largely restricted to advertising for fast-food restaurants and are more likely to appear as children rather than as teens or adults. In commercials directed to adults, Hispanic roles emphasize physical and sexual attractiveness to the exclusion of other characteristics. Although it is true that advertisers trying to target Spanish-speaking audiences can advertise on Spanish-language cable television, where there are many examples of Hispanic-only ads, this option does not minimize the potential impact of Hispanic stereotypes on mainstream Anglo television.

Asian Americans in advertising for both adult and children are presented in settings associated with work, are shown as part of a group, are associated with the technology, and have a limited number of speaking roles. They are most likely to appear in work settings in roles that suggest passive personality characteristics. In terms of status, Asians are unlikely to fill adult roles and are more likely to appear as children or teens in advertisements.

Advertisements also portray the ways in which members of diverse groups interact with each other. Integrated advertisements are more common in children's programming than in adult programming. These advertisements almost always include European Americans, reaffirming the group's majority status in the society. Mixed-race groups are typically presented in public settings like schools, playgrounds, or streets, rather than in home or social settings. The interaction among the participants is cooperative, shown in such situations as play with action figures or games.

EFFECTS OF RACE AND ETHNICITY IN ADVERTISING

The effects of advertising featuring diverse racial and ethnic groups have not been well studied with children and adolescents. In general, advertising with diverse characters does not have a negative effect on product preferences and purchases. Viewers express preferences and buy products advertised by diverse role models. However, research on television content and racial attitudes among youth suggests that young people learn about racial and ethnic groups after exposure to diverse characters. Long-term exposure to these presentations can affect their racial attitudes and perceptions. There is also evidence that children and adolescents will observe and imitate same-race and different-race models. Although the research on advertisements featuring diverse characters is limited, it is reasonable to expect that commercial content specifically designed to influence attitudes and behavior toward products can alter children's and adolescents' attitudes toward and perceptions of the various racial and ethnic groups presented in advertising.

ADVERTISING, EXPOSURE TO

Children's and youth's exposure to advertising has increased in virtually all media realms over time. Estimates of their exposure to television advertising rose from 20,000 ads per year during the 1970s to more than 40,000 ads per year during the 1990s. Throughout this time, the proportion of products represented and the character demographics in television advertising have remained remarkably stable.

In the early 1970s, a seminal research project by Earle Barcus surveyed and described the nature of television advertising directed toward children. The majority of commercials were categorized into four groups: toys, cereal, candy, and fast food. In the early 1990s, another research team found similar proportions of the amount of product advertisements. Comparable trends were found with seasonal peaks of toy advertisements at the end of the calendar year and in the use of fun and happiness themes associated with the product.

Although gender representations in commercials have been more equitable in recent years than in the past, with the number of boys and girls shown in ads being fairly equal, there are concerns about patterns of roles to which each gender is assigned. Stereotypical portrayals in ads continue; boys tend to be shown acting aggressively, and girls are shown in domestic roles. Voiceovers in commercials directed toward boys tend to use male voices, whereas female voices are used for ads aimed at girls. Depending on how a commercial portrays a product (e.g., boys shown playing with a particular toy), children are influenced in both attitude (i.e., male viewers prefer that particular toy more than girls do) and behavior (i.e., male viewers tend to play with a toy advertised with a boy). A recent study of video game ads in video game magazines revealed that representations of boys outnumbered those of girls three to one, and that more than half of the ads touted violent games, with an average of 2.5 weapons per ad.

Even though neither tobacco nor alcohol can be used legally by children, youth are exposed to persuasive messages about these products. In 2001, youth aged 12 to 20 years saw approximately 245 televised alcohol advertisements. Companies may attempt to target children through the use of animated characters such as the Budweiser frogs in television ads and Joe Camel in print media. Brand recognition studies show that, among some tobacco products, brands may be universally recognized among young children. Similarly, brand recognition increases along with the amount of advertising. Studies have examined youth's exposure to ads for alcohol in magazines. As with television ads, increased exposure to alcohol ads in magazines, although not necessarily intended for youth, relates to youth's increased intentions to drink alcoholic beverages.

Print media, such as magazines, also exert a steady influence on older youth. Studies have documented that 46% to 57% of popular teen girls' magazines are devoted to advertisements. Themes of idealized beauty and sexual suggestion predominate. Advertisements tend to focus on physical appearance, with the overwhelming majority being for clothes, cosmetics, and weight loss programs.

Advertising exposure via newer media such as the Internet is less clear. However, food product marketers now promote Web addresses on product packaging and in television ads directing children to their websites. Once there, youth may engage with advergames—video games where youth interact with a product, such as Dunk N' Slam Oreos. Marketers of such products use advergames as a way to increase children's familiarity with and subsequent preference for particular brands.

Advertising also penetrates grade schools. Channel One is a daily newscast shown in approximately 12,000 middle, junior, and high schools. Advertising on Channel One has been shown to enhance youth's cognitions about advertised products, to produce more favorable affect toward products advertised, and to increase intentions to purchase the advertised products.

Sponsored sports equipment and vending machines selling sugared drinks and high-density, low-nutrient snacks may be placed on school property to generate revenue for schools and expose youth to product advertising. Additionally, advertising now crops up in school textbooks. Images of food products, such as M&M's, have been used to teach children how to count.

ADVERTISING, GENDER AND

For parents, teachers, and gender studies scholars, a primary concern about print advertising is its stereotypical representation of males and females. As a part of the broader category of media, advertising plays a role in the socialization of its viewers. Children and teens, attempting to figure out who they are, are more susceptible than adults to the socialization powers of the media. Advertising in both print and television media can influence the self-images of youth and adolescents and can shape their views of the appropriate social roles for males and females.

Although some studies were conducted before the 1970s, research in the area of advertising stereotypes and effects grew rapidly in the 1970s. In 1979, Goffman pointed out that, in print advertisements, women were usually portrayed in submissive roles, family roles, or lower-status positions than men were, and they were likely to be depicted as sex objects. In print ads of the 1970s, women were usually housewives in decorative roles. They were rarely shown as professionals or in activities away from the home, and they primarily advertised products for home use.

Studies conducted since the 1970s have found that not much has changed. Although Sullivan and O'Connor (1988) found changes in women's social and occupational roles, they also found an increase in portrayals of women in decorative and sexualized roles in ads in general interest magazines such as *People, Newsweek,* and the *New Yorker.* A study of *Vogue, Mademoiselle,* and *McCall's* from 1979 and 1991 produced similar results. More recent studies have compared advertising in different types of magazines. Linder (2004) found that ads in the fashion magazine *Vogue* depicted women more stereotypically than did the ads in *Time.* An analysis of ads in white women's magazines showed women in roles and with characteristics that suggested dependency and submissiveness, whereas ads in magazines targeting black women portrayed women as independent and dominant. White women were more objectified than black women. Mastin et al. (2004) looked at the products advertised in *The Ladies Home Journal* and *Essence* and found that most related to appearance, children, and home. The authors noted that women's magazines continue to subject women to traditional images of women's lives.

GENDER STEREOTYPES ON TELEVISION

Researchers who examined gender roles in television commercials in the 1970s found gender stereotypes to be quite prevalent. Men were the spokespeople for all types of products except cosmetics and household products, and voiceovers were male at least 90% of the time. Women in commercials typically were housewives, but men had a variety of occupations. Courtney and Whipple's 1974 examination of four studies found that women were overrepresented in family and home settings and were most often seen performing domestic tasks. Men dominated advertising dealing with entertainment, business, sales, and management occupations, and they usually did not demonstrate products—rather, they were often shown benefiting from tasks performed by women.

More recent studies found both similarities and differences when comparing advertising in the 1970s with advertising in the decades since then. Women were still more likely to be the representatives for domestic products, and men were more likely to represent nondomestic products. Males performed 70% of voiceovers, compared with 90% in 1978. Pierracine and Schell (1995) also found a 70% decrease in male voiceovers as well as more atypical than stereotypical roles for women. Stereotypical roles included

homemaker, secretary, and nurse, as well as situations in which women were viewed as victims, nags, or scatterbrains, or in subordinate positions.

Rouner, Slater, and Domenech-Rodriguez (2003) examined the content of beer commercials and nonbeer commercials and found that a majority of the beer commercials contained traditional gender roles and sexist content. Nonbeer ads were evenly divided between sexist and nonsexist content.

GENDER ROLES IN CHILDREN'S ADVERTISING

Two studies looked at gender and advertising spokescharacters—the animated characters used as product representatives, such as Tony the Tiger and the Energizer Bunny. Spokescharacters are prevalent in advertising directed toward children. A 1999 study by Peirce and McBride found that most spokescharacters were male: 30 of 39 were male, 2 were both male and female, 2 were female (Mrs. Butterworth and Aunt Jemima), and 5 were judged neither male nor female. The neutral characters were Scrubbing Bubbles, Snuggles Bear, Cheerios Bee, 7-Up Dots, and Toilet Duck. In the second study (Peirce, 2001), participant ratings in an experimental setting indicated that male spokescharacters were not necessarily preferred by viewers. The spokescharacter was better liked when the gender of the spokescharacter matched the gender of the perceived target audience.

Maher and Childs (2003) undertook a longitudinal analysis of gender roles in children's television advertisements and found that gender stereotyping, although not quite as prevalent as previous decades, is still present in the 21st century. They determined that there is more gender equality in the ads targeting one sex or the other but that males still outnumber females as the dominant product users, voiceovers, and main characters.

EFFECTS OF ADVERTISEMENTS

If images in the media had no effect on audiences, these studies of representations in advertisements would be trivial. But research suggests that gender stereotyping does matter. Kilbourne, who has studied gender stereotypes in ads for 30 years, describes their impact on adolescent girls who lose self-confidence and self-esteem. Advertising, she says, contributes to these losses through its emphasis on physical beauty and thinness in females. The results among teens and preteens may include obsession with their looks and dangerous dieting practices undertaken in attempts to reach the female ideal. Citing expectation theory, Maher and Childs (2003) suggest that gender stereotyping in children's television advertising will be instrumental in shaping children's expectations of gender roles in a social context.

ADVERTISING, HEALTH AND

Children and adolescents are a major market force because of their spending power, purchasing influence, and value as future adult consumers. Given the high economic stakes, the number of commercial messages targeting youth is exploding. Multiple marketing techniques and channels are used to reach youth, including mass media advertising (e.g., television, magazines), online advertising, in-school marketing, product placements (in TV, movies, videogames, etc.), licensing of popular characters in movies and TV, and other promotions such as cross-selling and tie-ins. Messages are intended to build brand loyalty and promote product use, but they may also be selling unhealthy lifestyles and habits and contributing to a public health crisis. By influencing both intended and unintended health outcomes of America's youth, these messages play a key role in socializing children and adolescents as consumers, influencing their health decisions regarding eating behaviors, nutrition and obesity, and the use and abuse of tobacco and alcohol. A significant amount of research evidence has accumulated on the nature and prevalence of health-related advertising messages, the consequences of exposure to such messages in different age groups, and the implications for policy decision making.

THE NATURE AND PREVALENCE OF ADVERTISING MESSAGES

The vast majority of research on advertising to youth focuses on television advertising. It is estimated that the typical child sees nearly 40,000 television commercials a year, and upfront advertising spending in 2004 on children's network television alone was estimated to be more than $900 million. Although youth spend more time watching television than using other media, the paucity of research examining other media channels leaves a large gap in our knowledge of the role of advertising on young people's healthy and unhealthy lifestyles.

Television advertising influences children and adolescents in two ways. First, advertisers target children and adolescents directly as the *primary target audience* for products that are relevant to their demographic, such as food, toys, and entertainment (movies, music, etc.). These messages influence young people's purchase and consumption of products as well as the "purchase influence attempts" they make to parents. Second, children and adolescents are exposed to advertising indirectly as a *secondary audience* for products and services targeted to adults, such as alcohol, tobacco, and most medicines and drugs. Although much of this advertising is adult oriented and therefore less likely to appeal to or be attended to closely by youth, exposure to these messages may have long-term effects, so substantial research has examined the effects of young people's exposure to some advertising targeted to adults.

Changes in a child's or adolescent's consumer behavior may be due to cumulative exposure to ads with age, to learning from significant others, or to maturation and experience. Research on advertising to children grows from an understanding of key issues related to cognitive development, including how children understand advertising and how they are influenced by it, starting at the most fundamental level of information-processing tasks but also including the socialization process of youth. Critical factors include children's ability to discriminate between the program and the commercial, which involves recognition of the persuasive intent of the ad message, and advertising effects such as recall of ads, attitudes toward commercials, brand preferences, and desire for the advertised merchandise. Research also examines the role of production conventions (such as music) and different advertising strategies (such as the use of spokescharacters or celebrities) to enhance the effectiveness of advertising appeals to children.

For adolescents, development of the cognitive skills needed to process and fully understand information presented in commercials is not so much an issue. However, as the influence of parents diminishes, advertising may enhance consumer socialization, inducing youngsters to engage in adult behaviors such as smoking and drinking. Research suggests that television advertising does influence health-related knowledge and behavior of youth in negative ways.

However, because of variations in the methodologies and measures used, caution must be exercised in comparing the findings of studies.

CHILDREN AND ADOLESCENTS AS THE PRIMARY TARGET AUDIENCE

Children long have been seen as vulnerable to advertisers, and for a quarter-century televised food advertising targeted to children has been of critical interest to parents, researchers, and policy makers. According to the Center for Science in the Public Interest, fast-food and snack-food companies spend $10 to $12 billion a year in marketing to children and teens. Studies of advertising content of children's programming find that cereal, candy, and fast-food restaurants are three of the four categories constituting more than 80% of the ads. The majority of these commercials over the past 25 years have consistently promoted highly packaged and processed foods of low nutritional value.

The growing epidemic of overweight children has brought renewed attention to the possible role that food and beverage marketing activities may play in influencing eating behaviors of youth. According to Katherine Battle Horgen and her colleagues, studies reveal that children show more favorable attitudes toward, preferences for, and behaviors toward food products they see advertised. In addition, heavier viewing of television has been associated with less-healthy food choices, according to a review of 40 studies by the Kaiser Family Foundation. The report notes that the number of commercials for candy, snacks, and sugared cereals is far greater than the number of commercials for the healthier, more nutritious foods recommended by the USDA Dietary Guidelines. The general finding that eating habits formed during childhood often persist throughout life underscores the serious implications of such advertising.

CHILDREN AND ADOLESCENTS AS THE SECONDARY TARGET AUDIENCE

Dale Kunkel has reviewed the substantial body of research assessing the influence of commercials for sensitive products not intended for children, including alcoholic beverages and certain drugs and medicines. Although tobacco products are no longer advertised on television, there is a large body of research examining the influence of marketing and advertising in other media (e.g., out-of-home billboards, magazines) on children's and adolescents' attitudes toward, intentions to use, and actual use of these products.

Drugs and Medicines

With the pervasiveness of advertising for nonprescription (over-the-counter, or OTC) and prescription (direct-to-consumer, or DTC) drugs, it is inevitable that children and adolescents are indirectly exposed to these ads. In 2003, ad spending for drugs and medicines increased to slightly more than $12 billion. While drug advertising may provide consumers with information about the treatment of health problems, it may also encourage individuals to buy and use medications they may not need; furthermore, it may socialize young people to have casual attitudes toward drug use and to believe that physical and emotional discomfort can be ameliorated by "popping a pill." Although OTC drugs are claimed to be safe if used correctly, the notion of "correct use" (e.g., proper dosage, choosing the right medicine, etc.) is an area of concern for the youth audience, particularly because these products are readily available to young people. Indeed, some critics have argued that OTC ads may contribute to children overdosing on these drugs.

Three general areas have been investigated in previous research on drug advertising: the impact of advertising on brand choice and requests; the socialization of young people to view medicines as a palliatives; and the role of advertising as an "environmental influence" on illicit drug use (e.g., marijuana). In his review of research on children and television advertising, Dale Kunkel notes that, although some modest short-term effects on brand choice have been demonstrated, studies do not indicate any long-term impact on children's beliefs or attitudes about medicine use or on their requests to parents for medicine to cure their ills.

There is some support for the idea that advertisements shape children's views on the amount of societal sickness and reliance on medicines for the relief of ailments. These perceptions by youth may not be surprising, however, given that the content of OTC drug ads tends to focus more on what the drug will do for the consumer (i.e., consumer awareness of product as primary goal), rather than on the reasons why the drug should be ingested (i.e., an education about product attributes).

In their review, Anna B. Almarsdottir and Patricia J. Bush (1992) found several studies examining the role of OTC drug advertising in influencing illicit

drug use attitudes and behaviors among young people. However, they concluded that there was no substantive support for a causal link between exposure to OTC ads and drug abuse or other negative effects. Updated research focusing on the effects of OTC drug ads on children and adolescents is sorely needed.

Children and adolescents are also likely to be exposed to DTC advertisements, as expenditures for this type of pharmaceutical advertising have soared since 1997 from $900 million to $4.1 billion in 2004, with television advertising witnessing the most rapid growth. But there is a dearth of research on the influence of DTC advertising on young people. Although research on adults shows an increase in awareness of drug brands and an impact on their decisions about medications and communication with their doctors, whether similar outcomes might result for young people exposed to DTC advertising is a matter of speculation.

Tobacco and Alcohol

Underage viewers are also unintentionally exposed to advertisements for tobacco and alcoholic products. Susan Villani reports on numerous recent studies documenting that children and adolescents who are exposed to greater amounts of tobacco or alcohol advertising are more likely either to use or to intend to use such products. The evidence for this relationship between advertising and promotions and product consumption or intention to consume is strongest in the case of cigarettes. For alcohol, correlations have been only moderate. Research shows the influence of advertising on young children's recognition of brand logos, including logos for cigarette brands. Studies of older children that examine the relationship of various advertising and marketing techniques for cigarettes and alcohol to later susceptibility to smoking and drinking note that advertising for these products is associated both with beliefs about product use and with behavior. Researchers have also expressed concern about the frequent use in alcohol advertising of positive values linked with drinking, such as romance, sociability, and relaxation.

Countercampaigns

Critics often suggest a ban on advertising of products deemed to be unhealthy. However, some believe that counterads can be more effective, by educating young people about the negative effects of these products and dissuading them from unhealthy behaviors. At present, though, counteradvertising does not seem able to reach the density that mainstream advertising already has, thus making it less useful as a solution to counteract messages for alcohol, tobacco, food, and the like.

Over the past 50 years, health campaigning has increased steadily. However, according to a report by Charles Atkin, findings are mixed on the effects of public service announcements (PSAs) to increase awareness, reinforce positive beliefs, intensify personal concern, and facilitate behavior change. When used as part of a media campaign in tandem with multiple media channels and interpersonal interventions, PSAs can be moderately successful under certain conditions. With greater availability of funds, paid messages about illicit drugs, smoking, and alcohol are more frequent, although access to free media placements have diminished significantly.

Anti-smoking campaigns have shown some promise in decreasing teen smoking. In 2002, more than 21 states used paid anti-smoking advertising targeted to youths, funded primarily from the 1997 settlement between tobacco firms and the U.S. attorneys general. Although it is unclear whether recent declines in smoking among youth are due to these campaigns or to macro trends in tobacco use, a fundamental question is whether using any anti-smoking message makes sense from a public health perspective, compared to doing nothing at all. Drunk driving has decreased substantially over the past two decades, yet the only notable evidence of media effects in this area comes from programs that used media messages in conjunction with rigorous enforcement initiatives. Meanwhile, some groups continue to recommend stricter limitations on the amount of advertising on children's television, a ban on all tobacco and alcohol advertising in all media, and the use of PSAs targeted to adolescents as well as more involvement by parents in educating youth to be responsible and informed consumers.

FUTURE RESEARCH

Although issues of methodology may obscure research findings on the influence of advertising on child and adolescent health, the pattern of previous outcomes indicates that advertising reaching young audiences effectively influences their unhealthy attitudes toward and use of certain products. The challenges are many for future research, which should examine areas such as OTC and DTC drug advertising; control for other influences, such

as marketing activities other than advertising in media other than television (e.g., the Internet); examine differences in short-term versus long-term effects of advertising; better separate out social effects, such as the influence of peers and family; address whether and how television may contribute to positive consumer behavior patterns; and examine how critical television viewing skills might ameliorate negative effects. An open dialog between public health educators and advertisers is needed to determine whether and how it might be possible to work in tandem to achieve important health goals for youth such as those promoted by Healthy People 2010, the national health goals stated by the Centers for Disease Control and Prevention.

ADVERTISING, HOST SELLING AND

Host selling refers to a form of advertising that uses program talent, including animated cartoon characters and "live" program hosts, to deliver commercials. Such character endorsement may confuse children and keep them from distinguishing between program and nonprogram material. An example is an advertisement for *Bananas in Pajamas* toy characters airing during the children's program of the same name.

Host selling has been an area of concern for children's advocates for decades, largely due to children's nature as a special audience. Research suggests that children do not have the cognitive ability to differentiate between programs and ads until the age of 4 or 5, and do not recognize the persuasive attempt inherent in advertising until the age of 7 or 8. As a result, many feel that advertising to children can be unfair and have sought to regulate it.

In 1974, Action for Children's Television (ACT) petitioned the Federal Communications Commission (FCC) to require broadcast licensees to air an hour of educational programming for children each day, and to ban licensees from airing ads directed at preschoolers. In response to the petition and other pressure, the FCC issued a Notice of Inquiry (NOI) and two Notices of Proposed Rule Making (NPRM), eventually resulting in the Children's TV Policy Statement. Among other guidelines, the statement discouraged host selling and restricted program-length commercials (PLCs), a similar form of advertising in which commercials for a product are aired during a program associated with a product (e.g., a commercial announcement for a Sonic hand-held game broadcast during the *Sonic the Hedgehog* program). The statement was not a rule, and therefore violations of it did not result in fines. Rather, it was a license renewal processing guideline, suggesting that licensees who wanted the greatest likelihood of having their licenses renewed should adhere to it.

Due to its lack of enforcement powers, advocates of advertising restrictions were not entirely satisfied and continued to press the issue. As a result, Congress took the unusual step of funding an FCC Task Force in 1978 to examine children's television. In 1980, the FCC issued another NPRM to consider making the guidelines into administrative laws, or rules. However, the election of President Ronald Reagan in 1980 ushered in an era of deregulation and the relaxation, rather than codification, of the advertising guidelines.

Critics of advertising to children persevered, and in 1990 Congress passed the Children's Television Act of 1990. In addition to other provisions, the act's rules prohibit both PLCs and host selling, and they

apply to both commercial and noncommercial television broadcast stations (a noncommercial television station is impacted by the host selling policy if it airs a sponsorship announcement featuring the same characters that appear in the immediately adjacent children's program). The commercial limitations went into effect on January 1, 1992.

In 2004, the FCC revisited children's programming obligations to update them for the digital world. In addition to upholding the existing host selling and PLC rules, the new rules also ban host selling Web links or Web addresses that are promoted in a show and that use characters from that show to sell a product. These newer rules, which went into effect on January 1, 2006, are currently at the center of a legal battle in which Viacom, the parent company of children's television network Nickelodeon, is suing in federal court in Washington, D.C., asking that the rules be thrown out or remanded on the basis that they are unconstitutional and that they pose an economic hardship on stations that would be forced to redesign existing programming and websites. At the same time, the Office of Communication of the United Church of Christ, led by former FCC commissioner Gloria Tristani, filed suit in federal court in Cincinnati asking for a strengthening of the rules. With both activists and the TV industry threatening lawsuits, a compromise agreement was reached in December 2005 that eased some restrictions but maintained others. This was contingent on FCC agreement to the compromise. However, in March 2006, the FCC issued a second Notice of Proposed Rule Making about the matter and is currently collecting public comment on how the issue should be handled.

ADVERTISING, INTENDED VS. UNINTENDED EFFECTS OF

The effects of television advertising on children and adolescents can be divided into two general types: intended and unintended. Intended effects are the effects that advertisers wish to achieve with their advertisements, and unintended effects include the often-undesired side effects of advertising exposure.

INTENDED EFFECTS OF ADVERTISING

Intended effects research typically focuses on three kinds of effects of advertising on children: (1) cognitive effects, including children's awareness of brands; (2) affective effects, such as children's product preferences; and (3) behavioral effects, including children's purchase requests.

Cognitive Effects

Cognitive effects research focuses on children's recognition or recall of commercials and brands, which are often qualified as children's *brand awareness.* Both brand recognition and recall are usually operationalized by showing children a series of brand logos, brand characters, or commercials. In the case of brand recall, children are asked to name the specific brand when cued by the stimulus. In the case of brand recognition, they are invited to choose from a number of available options. It has been found that children's ability to recognize brands starts earlier in development than their ability to recall these brands.

Several studies have investigated the effects of advertising on children's brand recognition and recall. The studies on children's brand recognition have consistently found a relation between advertising and brand recognition. However, the relation between advertising and brand recall has been established only among older children and adolescents, not among younger children. A possible explanation for this developmental difference is that most recall tasks, particularly those in which children have to come up with the brand names themselves, are too difficult for younger children and are perhaps so difficult that advertising has no or little effect on their brand recall.

Affective Effects

Affective effects studies concentrate on children's attitudes toward and preferences for commercials and brands. Even very young children have distinct ideas about what they do and do not like. Studies examining the relation between advertising and brand preferences have shown that exposure to advertising can affect children's brand attitudes, although this does not necessarily occur. Children's attitudes toward brands are determined by many factors, including their gender, cognitive level, media preferences, and susceptibility to peer influence. It has been shown that that the most crucial predictor of children's brand attitudes is whether they like the commercial.

Behavioral Effects

A third type of intended effects research investigates the extent to which children are persuaded by advertisements. Because young children generally do not have the means to purchase products, behavioral advertising effects are usually measured by means of children's product requests to parents or their Christmas wishes. Studies of the effects of advertising on children's request behavior have consistently demonstrated that children who watch commercial television ask their parents for advertised products more often. In addition, children's advertising exposure highly predicts the number of requests for advertised products on their Christmas wish lists.

UNINTENDED EFFECTS OF ADVERTISING

Unintended advertising effects encompass the often-undesired side effects of advertising. Unintended effects studies have investigated, for example, whether advertising stimulates materialism, parent-child conflict, unhappiness, and bad eating habits.

Materialistic Values

Several authors suggest that advertising stimulates materialistic values in children. According to these authors, advertising enhances materialism because it is designed to arouse desires for products that would not otherwise be salient. Advertising propagates the ideology that possessions are important and that desirable qualities—such as beauty, success, and happiness—can be obtained only by acquiring material possessions. Several studies have established the relation between exposure to advertising and materialistic values in children as well as adolescents.

Parent-Child Conflict

It is often assumed that advertising contributes to conflicts between parents and children. The underlying idea here is that advertising encourages children to ask for the advertised product. Because parents do not want to comply with all these product requests, they have to say no to their children more often. As a result, the chance of conflicts between the parent and child increases. Studies on advertising-induced conflict have consistently found positive relations between advertising exposure and purchase requests and between purchase requests and parent-child conflict.

Dissatisfaction and Unhappiness

Some researchers believe that advertising can make children unhappy. First, it is assumed that advertising paints a world full of beautiful people and desirable products. If children watch too many commercials and compare them to their own situations, the contrast between the two worlds can make them unhappy. Although there is some evidence that exposure to beautiful models in magazines can negatively affect the self-perception of teenage girls and boys, the relation between exposure to advertising and unhappiness has never been established among younger children.

A second way in which advertising may affect children's happiness involves the manner in which children's products are presented in commercials. By using camera and editing techniques that are not well understood by young children (e.g., close-ups, moving images of toys that do not themselves move), commercials can create high expectations about the actual performance and quality of the product. If the product is a disappointment after purchase, children can become frustrated and unhappy. However, although one study has found a small relation between exposure to advertising and children's dissatisfaction with products, the research is too scarce for decisive conclusions to be drawn about this unintended effect.

Advertising Enhances Bad Eating Habits

Finally, it is often assumed that advertising creates wants for advertised food products that may endanger children's health. A large share of child-directed advertisements promote high-calorie products, including candy, soft drinks, and fast-food restaurants. Consequently, advertising is often considered one of the causes of the dramatic increase in obesity among children over the past decades. Several authors have argued that exposure to advertising increases the consumption of unhealthy products, which in turn leads to obesity among children and adolescents. In line with this assumption, several studies have found weak to moderate relations between children's advertising exposure and their diets, overweight, and obesity.

ADVERTISING, MARKET SIZE AND

In 2003, the American Psychological Association (APA) estimated that marketers spend more than $12 billion a year on television commercials aimed at children and adolescents and that the typical child, regardless of age, views more than 40,000 commercials each year. This occurs despite Federal Communications Commission (FCC) limits of 10.5 minutes of advertising per hour on television during weekends and 12 minutes on weekdays in programming aimed at children. Even those limits are occasionally violated, as indicated by the $1 million fine the FCC levied against Nickelodeon Channel owner Viacom and the $500,000 fine against ABC Family Channel owner Disney for violating the FCC children's commercial restrictions.

Another indicator of the size of the market is the $10 billion that U.S. Senator Harkin (D-Iowa) claimed in 2005 is spent by the food industry each year on advertising targeted at children. In a 2005 announcement that it was voluntarily halting all television advertising of foods it considered unhealthy for children under 12, Kraft Foods, one of the largest advertisers in the country, noted that it spent about $90 million annually on such advertising. The company has a policy of not advertising to children under 6 years of age.

Advertisers are interested in reaching children and adolescents because they are a large and growing market. For example, American adolescents are estimated to spend some $140 billion a year, and children 12 and younger are said to spend $25 billion. The latter are believed to exert influence over parents in an additional $200 billion in spending. A 2005 study by Simmons Market Research found that teenagers spend an average of $458 million a week. A report in *Business 2.0* magazine estimated the amount teenagers spend as much higher at $94.7 billion for goods and services.

Commercials have become so pervasive on television that one major cable company launched a 24-hour digital cable channel for preschoolers in 2005. It includes commercials before and after programs, most of which were originally broadcast on PBS, such as *Sesame Street* and *Barney and Friends.* The prevalence of such advertising led the American Psychological Association to issue a 2005 report recommending that the federal government restrict marketing aimed at anyone 8 or younger. A 2005 study by University of Illinois at Urbana-Champaign researchers found an average of 10.65 food advertisements in a sample of TV ads, leading the authors to conclude that 6-to-11-year-olds view about 11,000 such ads each year, more than one third of which are for fast food and convenience foods. Many nutritionists attribute the growing problem with overweight students to the increased consumption of convenience foods and fast foods.

ADVERTISING, MATERIALISM AND

Whether advertising increases materialism, particularly in children, is a question that has been asked frequently over the years but especially since the inception of mass media advertising. However, concern has increased primarily since the advent of television advertising, which gave marketers much greater access to children's attention and comprehension. The concern appears to have taken on even more urgency in recent years as the number of dollars spent on marketing to children has skyrocketed. Children are a lucrative segment for marketers, not only because they have their own money to spend but also because they are also becoming increasingly influential in the purchase decisions of their parents.

Yet, despite the seemingly obvious anecdotal evidence that parents, teachers, and even health-care professionals provide that suggests clear increases over time in children's desire and requests for more "stuff," good empirical evidence that attests to the relation between advertising and materialism for children is remarkably scarce. This scarcity can be attributed to a number of issues, but two in particular are noteworthy: the difficulty in understanding precisely what is meant by *materialism* (and thus measuring it) and the difficulty of doing research on children.

With respect to defining and measuring materialism, is materialism (and its relation to advertising) reflected by an increase in product requests by children after they have been exposed to increasing levels of advertising? Is it reflected in more positive attitudes and greater desire for products after greater exposure to advertising? If it is, then the answer is easy: Advertising clearly leads to these outcomes, and this assertion has been documented in a number of well-controlled studies. However, materialism is typically conceptualized as involving something deeper than short-term desires and attitude change. Specifically, materialism is generally thought to be reflected in more deeply seated traits such as envy, jealousy, or lack of generosity, or in value system compositions in which the attainment of material goods and wealth is central to the individual and is seen as a prerequisite to success and happiness.

The second problem, the difficulty of conducting research with children, is equally important. Aside from the ethical issue of whether exposing children to massive (or even small) doses of advertising is worth the knowledge to be gained from experimentally assessing outcomes, there are daunting problems of measuring materialism in children. One such problem is that deeply rooted beliefs, such as those embodying personal values, may not yet have formed in the early stages of childhood. Another concern is that, even if values and value systems have been sufficiently formed, children may not yet have the ability to fully articulate them. Consequently, researchers are often left with more short-term, "early indicators" of developing materialism such as those identified earlier (e.g., attitude change, desire, preference, frequency of product requests).

Nevertheless, despite these problems, good research does exist that can speak either directly or indirectly to the issue of whether advertising influences materialism in children. Some of this research pertains to how children comprehend advertising and whether they are able to combat its effects. Other research pertains directly to the link between advertising and materialism.

CHILDREN'S COMPREHENSION OF ADVERTISING

Some researchers have examined whether children have the ability to comprehend advertising and its

intent. This topic has played a part in one of the primary arguments for regulating, if not banning, advertising to children, for one could argue that children's inability to understand advertising can have damaging effects. This issue is generally viewed as involving two questions: first, whether children can distinguish commercials from programs (in the case of television), and, second, whether they understand what advertising is trying to do, even if they can distinguish it from other programming. The first question is a function of how children develop cognitive skills as they age. Drawing on Jean Piaget's framework of cognitive development, Deborah Roedder John (1999) characterized children's cognitive development as moving through three stages of information processing ability: cued processors (under 7 years), limited processors (ages 7–11), and strategic processors (age 12 and older). Cued processors tend to distinguish objects on the basis of perceptual cues such as size, whereas limited processors and strategic processors are able to use a number of dimensions to reason about a stimulus in a thoughtful and abstract manner. Limited processors differ from strategic processors in that they are not generally as skillful in accessing and using prior knowledge to think about the implications of a stimulus such as advertising.

This general framework fits very nicely with the research to date on children's comprehension of advertising. For example, some research shows that children can actually distinguish ads from television programs at a very early age. One study found that preschool children could distinguish the program *Captain Kangaroo* from ads within the program (70% for 4-year-olds; 90% for 5-year-olds). However, this discrimination appears to have more to do with the structural differences between ads and programs ("Ads are shorter," children will report) and less with comprehension of what advertising means. In that same study (as well as many others), those same children were unable to explain the difference between the ads and the programs. As children enter the limited processing stage (around age 8), they begin to develop a fairly clear sense of the persuasive intent of messages, but unfortunately they are not always adept at using this knowledge as a defense against persuasive ads. Controlled experiments have shown that, even when children are clearly made aware of advertising's persuasive intent, such awareness had little to no effect on evaluations of the advertised products by first and second graders nor fifth and sixth graders.

ADVERTISING AS A CAUSE OF MATERIALISM

The question is, does exposure to advertising (because of or in spite of children's inability to distinguish or combat its purpose) result in increased levels of materialism? There is some evidence that it does. In a field experiment, research by Bradley Greenberg and colleagues (1993) showed not only that high school students exposed to advertising via Channel One programming were likely to evaluate the advertised products more highly than those not in the Channel One program, but also that students exposed to Channel One exhibited more materialistic attitudes than students who were not exposed (e.g., they more highly endorsed the notion that money leads to happiness). In another study of 9-to-14-year-olds, Marvin Goldberg and his colleagues (2003) found that materialism was positively correlated with frequency of viewing commercials, interest in commercials, and favorable response to celebrity endorsers. In yet another study, this one on adults, L. J. Shrum and his colleagues (2005) found that level of television viewing in general was positively correlated with materialism, which in turn led to less happiness.

Overall, the convergence of research on the relation between advertising and materialism is compelling. Moreover, research also shows a clear *negative* relation between materialism and general well-being and happiness. Perhaps for this reason, as well as the inability of children to adequately combat advertising messages, a number of countries or provinces, including Sweden, Norway, Greece, and Quebec (Canada) have either banned or severely restricted advertising to children. Such a ban was proposed by the United States Federal Trade Commission in 1978, but the ban was ultimately defeated.

ADVERTISING, PARENT-CHILD CONFLICT AND

It is often assumed that advertising contributes to conflicts between parents and children. The underlying idea here is that advertising encourages children to ask for the advertised products. Because parents do not want to comply with all these product requests, they have to say no to their children more often. As a result, the chance of conflicts between the parent and child increases.

Studies of the effects of advertising on children's request behavior have consistently demonstrated that children who often watch commercial television ask their parents for products more often. In addition, there is also evidence of a relation between children's advertising-induced purchase requests and the occurrence of parent-child conflicts. However, researchers have suggested a number of child and family variables that may affect the relation between advertising and parent-child conflict.

CHILD INFLUENCES

The chance of parent-child conflict as a result of children's advertising exposure may vary for children in different age groups and for boys and girls.

Age

Younger children make more advertising-induced purchase requests and come into conflict with their parents about advertised products more often than do older children. There are several explanations for this moderating effect of age. Research has shown that younger children are more vulnerable to persuasive information, because they have less experience and domain-specific knowledge that they can use while processing commercials. They are, therefore, less able to come up with critical thoughts and counterarguments while watching commercials, which enhances the likelihood that they will ask for advertised products.

A second reason for a stronger effect of advertising on parent-child conflict among younger children is that younger children more often have difficulty delaying gratifications than do older children. If young children see something as attractive, they focus all their attention on the enticing aspects of this stimulus and find it very difficult to resist, which may increase the chance of parent-child conflict.

Finally, the decrease in advertising-induced parent-child conflict with age may be a result of children's growing ability to apply sophisticated persuasion techniques. Research has shown that young children quite often ask, whine, and show anger in order to persuade their parents. Older children, in contrast, tend to use more sophisticated persuasion techniques, such as negotiation, flattery, and white lies. Such sophisticated persuasion strategies generally lead to less parent-child conflict than the persuasion strategies of younger children do.

Gender

The effect of advertising on parent-child conflict is often stronger for boys than for girls. Boys are generally more persistent in their requests for advertised products than girls are. They more often rely on forceful or demanding strategies when trying to persuade their parents, whereas girls are more likely to rely on tact and polite suggestions. The subtle persuasion strategies used by girls may decrease the chance of parent-child conflict.

FAMILY INFLUENCES

In addition to child variables, the relation between children's advertising exposure and conflict with their parents is moderated by two family variables: socioeconomic status and family communication processes.

Socioeconomic Status

The chance of advertising-induced parent-child conflict is generally higher in families with low socioeconomic status (SES) than in higher-status families. There is evidence that children from low-SES families make more advertising-induced purchase requests than high-SES children do. One explanation for this difference is that low-SES children tend to watch more television, which may stimulate their advertising-induced purchase requests behavior. Another explanation is that parents of low-SES families discuss advertising effects with their children less often than high-SES parents do, which may put low-SES children at a disadvantage in protecting themselves against advertising influences

In addition, there is evidence that the relation between purchase requests and parent-child conflict is stronger in low-SES than in high-SES families. This means that a request made by a child in a low-SES family more easily results in a parent-child conflict than a request made by a child in a high-SES family. One explanation might lie in the likely higher refusal rate due to limited monetary resources in lower-SES families. Another explanation might be that low-income parents employ less sophisticated strategies for conflict resolution. It has been demonstrated, for instance, that parents in low-SES families more often use coercive methods to deal with family conflicts than parents in high-SES families do.

Family Communication Processes

Finally, the effect of advertising on parent-child conflict is moderated by family communication processes. By discussing consumer matters and advertising content, often referred to as *parental mediation*, parents are able to increase their children's defenses against advertising and to mitigate advertising-induced purchase requests. Two types of communication processes regarding children's advertising exposure have been identified in the literature: *active mediation* and *restrictive mediation*. Active mediation is focused on family discussions about advertising and consumer matters, whereas restrictive mediation is mainly focused on obedience and protecting children from advertising.

The chance of advertising-induced parent-child conflict is considerably lower in families that often discuss consumer and advertising matters than in families that attempt to prevent children from watching commercials. It has been suggested that active mediation is more effective in counteracting advertising effects because it actively teaches children to become critical consumers, which in turn may reinforce their defenses against advertising. Restrictive mediation may be less able to counteract the effects of advertising because it does not teach children about advertising and consumer matters and thus does not help them to learn and apply defenses against advertising.

ADVERTISING, PERSUASIVE INTENT OF

The child's understanding of the persuasive intent of advertising has been an issue in the literature on advertising and marketing to children for more than 30 years. Why should this be so? In the early 1970s, various lobbying groups in the United States were concerned about the content of television advertising to children and petitioned first the Federal Communications Commission (FCC) and then the Federal Trade Commission (FTC) to regulate advertising to children and, as the movement took hold, to ban advertising to children. The years since then have seen similar flurries of concern coming and going on a global scale, culminating in the recent anxieties about food advertising to children in the light of a worldwide increase in obesity. One of the arguments put forward was that children were vulnerable to advertising and,

in particular, to the persuasive techniques used. In essence, the issue was whether commercial advertisements were inherently unfair and deceptive when aimed at young, impressionable children. If children cannot understand the intent behind advertising, there is a good case that it is unfair to allow advertising to be directed to them. Psychologists and other professionals can contribute to this debate by finding out the age at which children do understand.

It is, however, difficult to establish an age at which it can be said that most children understand the intent of advertising. The concept of *advertising literacy* suggests that several different abilities are required to understand advertising, and each of these can have its own trajectory of development with different rates for different children. We do know that most young children younger than about 6 years of age see advertising as merely entertainment. By 8–9 years, most children, when interviewed, will claim that advertising "tries to get you to buy stuff," and often this is cited as evidence that children understand the commercial and persuasive functions of advertising. By early adolescence, skepticism toward advertising has developed fully. The question of what happens between these ages is less easily answered. It seems that children begin to realize that advertising provides information, as well as being simply fun, at about 7 years of age, but an understanding that this information is persuasive emerges later. Just knowing that information about brands and products is being provided, without an understanding that it is designed to get the audience to purchase, is evidence that children are potentially at risk at that age. Knowing that advertising provides selective information—information that gives only positive information about the brand—is an ability that seems to emerge at about 7 years of age, with most children able to recognize that advertising does not say negative things about brands by 8–9 years.

So does this mean that the answer can be found in the evidence? The answer must be yes, and we now know that an approximate age of 7–8 years is crucial in terms of an emerging ability on the part of the child to discern and evaluate the advertiser's persuasive intent. There is an emerging consensus in the literature that children under the age 8 or thereabouts cannot really understand that the intention of advertising is to persuade and influence buying behavior, and some children show only a dangerous partial understanding—they may think that it is simply information about brands. So should we protect younger children from advertising but place no restrictions on advertising to adolescents and older children because they are no different, in this respect, from adults? The situation is more complex. There is no consensus on any single definitive age as the time when advertising is understood. However, research suggests that younger children understand the intent of advertising better now than in previous years, which would suggest that children are getting more sophisticated with advertising. But there is another more sobering finding. Samples used have been limited to predominantly white children. When African American children were sampled, the lack of awareness of the purpose of advertising was considerably greater.

Knowing something does not necessarily mean that one will put that knowledge into practice, and this is particularly the case with children. Debbie John, in an authoritative review in 1999, argued that younger and older children process and use information in different ways. Children under 7 years of age are seen as limited processors. In the language of information processing, children have mediational deficiencies that make storage and retrieval difficult even when they are prompted and cued to do so. Children over 12 years of age, on the other hand, are able to use various strategies for storing, retrieving, and utilizing information, and that can be done in the absence of prompting and cueing. Between the ages of 7 and 11, however, although children might be able to deploy strategies to enhance information storage and retrieval that are similar to those used by older children, they need to be aided by explicit prompts and cues. This suggests that, even if children understand intent, they will not be able to use this understanding and cognitively defend against advertising in all circumstances and contexts until 12 years of age.

In summary, research evidence has established that preschool children see advertising as existing only to entertain. Children gradually acquire an understanding of advertising, and most children have an adequate understanding of the intent behind advertising by 9 years of age. However, it is not until 12 years of age that children are able to use this understanding independently of external cues to defend against these persuasive messages.

ADVERTISING, PROGRAM-LENGTH COMMERCIALS IN

The marketing of toys associated with characters and themes of popular television shows is now commonplace. Television advertising, however, has transcended the 30-second commercial. Television programs themselves have become part of the marketing effort through program-length commercials. Dale Kunkel defines program-length commercials as programs that are originally conceived as vehicles for promoting products to the child audience. The purpose is to create awareness of a product line (e.g., GI Joe action figures) with the goal of increasing product sales and program popularity.

Historically, a television program was created to entertain or inform the viewing audience, with marketing of products to follow if that program was successful. In the case of program-length commercials, the creative process may be reversed (i.e., creating the product and then the program), or program and toys may be developed simultaneously. Within the literature, several terms are used to describe this phenomenon: *program-length commercial, product-related programming, toy-based programming,* and *toy-based cartoons.* These terms are used interchangeably in this entry.

HISTORY OF THE PROGRAM-LENGTH COMMERCIAL

In response to complaints and subsequent research about excessive advertising targeting children, the Federal Communications Commission (FCC) created policies in 1974 that required broadcasters to limit the amount of advertising during children's programs and to clearly separate commercial content from program content. This meant that program-commercial separation devices (also called *bumpers*) should be used, that host selling was inappropriate, and that product-related programming was prohibited. In 1983, the FCC then reversed many of its earlier policy decisions. During this period of deregulation, it was argued that marketplace forces would provide adequate regulation. Program-length commercials were legitimized, and they significantly increased in number during the mid- to late 1980s. Popular programs included *He-Man & the Masters of the Universe* and *Teenage Mutant Ninja Turtles.* In addition to government deregulation, Kunkel describes a convergence of factors, including structural changes in the broadcasting industry, new strategies for financing and distributing programming, and significant growth of toy marketing, as important contributors to the program-length commercial phenomenon.

Some years later, in response to the Children's Television Act of 1990, the FCC reinstated the ban on program-length commercials; however, it also changed the definition of this type of programming. The program-length commercial was more narrowly defined as a program associated with a product in which commercials for that product are aired. This new definition excluded product-related programming separated from the related toy advertisement by filler content (the norm).

EFFECTS OF PROGRAM-LENGTH COMMERCIALS

The research examining children's understanding of advertising in general demonstrates that children below about age 5 have difficulty discriminating programs from advertisements and that not until around age 7 or 8 do they recognize the persuasive intent underlying advertising. Interestingly, younger children tend to distinguish an advertisement from a television program

based upon perceptual features (e.g., ads are shorter than programs) rather than conceptual differences (e.g., ads are persuasive and programs are entertaining). Content analyses have established that program-length commercials share many of the same formal features used in traditional advertisements, hence exacerbating confusion children may experience.

Researchers have investigated the effects of program-length commercials with particular attention to discrimination between program and advertisement, recognition of persuasive intent, and influence on children's play behaviors. Barbara Wilson and Audrey Weiss (1992) randomly assigned 94 females ages 4–11 to one of three conditions: a cartoon immediately followed by an ad relating to cartoon content (adjacent condition); a cartoon immediately followed by an unrelated ad, but with a related ad shown earlier (nonadjacent condition); or ads shown with unrelated cartoons (control condition). The advertising used in the study consisted of (1) *Popeye* cartoon, Froot Loops ad, *Beetlejuice* cartoon, and *Beetlejuice* ad (adjacent condition); (2) *Beetlejuice* cartoon, Froot Loops ad, *Popeye* cartoon, and *Beetlejuice* ad (nonadjacent condition); and (3) *Popeye* cartoon, Froot Loops ad, different *Popeye* cartoon, and *Beetlejuice* ad (control condition). Young children (4–6 years) were less able to distinguish a toy advertisement from a toy-based cartoon when viewed in the adjacent or nonadjacent condition. Older children (7–11 years) did not demonstrate this confusion. Wilson and Weiss emphasized that perceptual features seemed to overwhelm other types of cues that younger children frequently use in making discrimination judgments.

In addition to difficulties with program-ad discrimination, research indicates that program-length commercials and their related toys have detrimental effects on children's imaginative play. One can easily see how the advertised toys may act as visual cues for the story lines and actions the children have just watched in the associated television programs, thereby leading to imitation rather than imagination. Patricia Greenfield and colleagues (1993) explored this issue by asking first- and second-grade children to tell a story using specific toys (Smurfs or Trolls) both before and after viewing a product-based cartoon (Smurfs) or playing a dot game. Imagination was defined as any form of representational activity that creates entities or events not found in the toy-based cartoon.

The findings revealed that the combination of toy-based cartoons and their related toys resulted in the lowest proportion of creative imagination (i.e., parts of the child's story were not found in the preceding toy-based cartoon) and conversely the highest imitation; the combination of toy-based cartoon plus neutral or unrelated toys yielded intermediate proportions of creative imagination; and the combination of a game plus cartoon-related toys yielded the highest proportions of creative imagination. The effect was strongest for first-grade children and did not exist for second-grade children. Toy-based cartoons in combination with the related toys had stronger detrimental effects on imaginative play than did the cartoon-related toys themselves. Notably, the content (Smurf cartoon) was prosocial in nature and was imitated by the children during their play. As Greenfield and colleagues suggest, the serious implication of this finding surrounds the types of characters presented in many program-length commercials. Antisocial television models will also be incorporated into children's play.

ADVERTISING, PURCHASE REQUESTS AND

Over the past two decades, marketers of toys and children's products have developed a diverse spectrum

of strategies to reach the child consumer. An important explanation for the increased interest in children is that the marketing world has discovered that today's children represent three different markets. First, they form a *primary market*. They have considerable amounts of money to spend on needs and wants of their own, which qualify them as a significant primary market. Children, however, also form an *influence market* in that they have considerable influence on family purchases. Not only do they give direction to the selection of food and snacks, they also have a say in the choice of restaurant or the make of the new car. Finally, they represent a *future market*. Adults often remain loyal to the brands they liked when they were children. When manufacturers influence the brand attitudes of children, there is therefore a considerable chance that these favorable attitudes will last into adulthood.

The fact that children have been discovered as three markets in one has major consequences for the commercial environment of children. For example, the amount of television advertising aimed at young children has increased considerably in the past decades. At present, there is more advertising aimed at young children than at teenagers. In addition to advertising, marketers of children's products increasingly utilize other, less obvious marketing practices that usually create less irritation among parents and adults, such as sponsoring of children's media entertainment or product placement. The frequent drinking of Coca-Cola in some comedies or soaps is an example of product placement.

To what extent does exposure to advertising increase children's purchase requests? The studies that have been conducted to date all demonstrated that children who often watch commercial television ask their parents for products more often (see Buijzen & Valkenburg, 2003, for a review of these studies). In the majority of studies, the reported correlations were around $r = .30$. This correlation coefficient means that children who watch commercial television at above-median levels have, on average, a chance of 65% of asking for advertised products, whereas children who watch at below-median levels have, on average, a chance of 35% of asking for products. Such a difference in the request behavior between light and heavy watchers of commercial television is, of course, very important to advertisers and marketers—certainly important enough to invest large amounts of money in extensive advertising campaigns for children's products.

ADVERTISING, REGULATION OF

Advertising can facilitate a free flow of information about goods and services that stimulates competition among firms and is crucial for the function of a market economy. Within a capitalist economic system, advertising is also a valuable source of information for consumers who buy products and services. Although advertising helps market performance by transferring useful information to consumers and by allowing firms to compete with each other to provide better and cheaper products and services, it may at times convey unfair, deceptive, or fraudulent messages to consumers. Thus, there is a need to regulate advertising to promote fair and useful advertising for firms and consumers as well as to counteract the negative effects of deceptive messages on market performance. Because a number of industries now target children and adolescents with advertising in a variety of media, the government—through the Federal Trade Commission—has addressed special efforts that may be needed to counter deceptive advertising toward young people. The advertising industry itself has also implemented measures to address such practices.

THE FREEDOM OF COMMERCIAL SPEECH AND REGULATION OF ADVERTISING

Before the 1970s, the courts generally ruled that advertising was not entitled to any protection under

the First Amendment. In a series of decisions during the 1970s, however, the U.S. Supreme Court made several landmark decisions that clearly stated that advertising can be protected under the First Amendment as a form of speech. For example, in *Virginia State Board of Pharmacy v. Virginia Citizens Consumer Council* (1976), the Court voided a statute that made it unprofessional conduct for a licensed pharmacist to advertise the prices of prescription drugs. In ruling on a suit brought by consumers to protect their right to receive such information, the Court held that it is in the public interest to have such information about prices. The Court later held that lawyers, too, had the right to advertise prices.

Advertising, or *commercial speech,* as the Court termed it, however, is protected to a "lesser degree" under the First Amendment than other forms of speech such as political or individual speech. The Court has made it clear that commercial speech is linked inextricably to commercial activity, and thus such speech is entitled to a limited measure of protection. This leaves room to regulate advertising under certain circumstances.

TYPES OF ADVERTISING REGULATION

By the early 1990s, the marketplace had become more complex. Consumerism and government regulations brought an end to a market governed by the classical libertarian principle of *caveat emptor,* "let the buyer beware," which put the responsibility for ensuring product quality and interpreting product information on the consumer who bought the product or service. The marketplace is now under the principle of *caveat venditor*, "let the seller beware," which puts the responsibility on the seller of the product or service. Thus, the government and the marketplace as a whole regulate product information, including advertising, to protect consumers as well as competition.

Advertising regulation comes from many sources. The most stringent regulation of advertising is by the federal and state government agencies that enforce the laws enacted by Congress or state legislatures. There are other institutions and organizations that regulate advertising. Consumer groups, for example, are a powerful force that regulates advertising by putting pressure on firms regarding truth and ethics in advertising. Individual advertisers and advertising agencies regulate advertising by self-policing advertising contents. Media firms also regulate advertising by screening the advertisements before placement.

Government Agencies

Federal and state agencies regulate advertising by enforcing laws relevant to advertising, but federal regulation is far more important and powerful than state or local level regulation. Although many different branches of the federal government regulate advertising, the most influential federal agency is the Federal Trade Commission (FTC). It is the most influential government agency regulating advertising not only because it has more policing and preventive power on deceptive advertising than any other government agency but also because other regulatory institutions, such as the courts and such self-regulatory bodies as the National Advertising Division (NAD) and the Children's Advertising Review Unit (CARU) of the National Advertising Review Council (NARC), use the guidelines the FTC has established. The FTC's primary task is to police and prevent unfair and deceptive business practices, including advertising. Once an advertising practice is found to be unfair or deceptive, the FTC can impose legal actions such as a consent order, a cease and desist order, or corrective advertising. The FTC may also publicize the case by posting it on its website or by releasing a statement to the press. Other federal agencies include the Federal Communications Commission (FCC), the Food and Drug Administration (FDA), the United States Postal Service (USPS), the Bureau of Alcohol, Tobacco and Firearms (BATF), and the Securities and Exchange Commission (SEC). Unlike the FTC, however, most federal agencies' regulation of advertising is limited by type of media or type of product.

Essentially, the FTC examines advertising practices from the target consumer's point of view. For example, an ad targeted toward teenagers will be examined from the teenagers' point of view, while an ad targeted toward the elderly will be examined from their perspective. In deciding whether an ad is deceptive, the FTC asks how a "reasonable person" would interpret an ad, where the reasonable person is considered to be to a consumer of average prudence and ordinary sense who uses ordinary care and skill. Historically, however, the FTC has paid special attention to "vulnerable" consumers, or audiences such as children, minorities, people who are sick, and the elderly. Specifically, the FTC applies a higher level of scrutiny in examining ads targeted to these vulnerable groups. For example, the FTC will pay special attention to advertising targeted toward children under

13 because children lack the analytical abilities and judgment of adults in receiving advertising messages. Some critics feel that these specially protected classes are too narrowly defined and should include other vulnerable groups. For example, they argue that teenagers older than 13 are also more vulnerable because they may not have fully developed analytical abilities and judgment skills, yet no specific legal and governmental protection is directed toward them.

In addition to regulating advertisers, advertising agencies may also be held legally responsible for misleading and deceptive claims in advertising. The FTC, for example, looks at two criteria in determining whether the advertising agency should be held liable for misleading and deceptive contents in advertising. Specifically, the FTC examines the extent of the agency's participation in the preparation of the advertisement and whether the agency knew or should have known that the advertisement included false or deceptive claims. If the agency meets either of these two criteria, it will also be held liable, and the FTC will take appropriate actions toward the agency.

Consumer Groups

The consumer movement gained much power during the 1960s and 1970s partly due to militant leaders such as Ralph Nader. Many consumer groups today are well-organized and equipped with the human and monetary resources to exert social pressure on business. The primary concern of most consumer groups is to secure the rights and power of consumers. One distinctive aspect of the consumer movement is that consumer groups at times regulate or attempt to control advertising on the basis of ethical concerns such as sexual content in advertising. All other regulatory institutions, such as government agencies or self-regulatory organizations, generally cannot regulate advertising based on ethical concerns. Further, unlike other regulatory forces, the actions of consumer groups tend to be swift and powerful. With government regulation as well as industry self-regulation, it generally takes a lot more time to reach a final decision and to impose sanctions on advertising, because of the procedures that must be followed. Consumer groups, however, can quickly organize boycotts, and they can quickly release negative publicity once a decision is made.

Self-Regulation

Self-regulation is a form of private regulation in which the industry voluntarily reinforces rules of behavior among member companies. Self-regulation is undertaken by advertisers, advertising agencies, and media to protect the member companies and the consumer from deceptive or problematic advertising content.

In the Unites States, the most notable self-regulation programs are the ones undertaken by industry groups and trade associations. For example, the Council of Better Business Bureaus self-regulates local advertising, and NAD and CARU self-regulate national advertising. NAD routinely monitors all forms of national advertising to ensure truth and accuracy of national advertising to adults, and CARU monitors and receives complaints about national broadcast advertising directed toward children under the age of 12. CARU has been successfully reinforcing its Self-Regulatory Guidelines for Children's Advertising. These guidelines require that advertisers should be sensitive to the level of knowledge and sophistication of children. The guidelines also urge advertisers to make a constructive contribution to the social development of children by emphasizing positive and constructive social norms in content of advertising.

Advertisers and advertising agencies exercise control over the advertising they produce. Because advertisers are responsible for the content in advertising, many advertisers have internal or external legal staff who screen all product claims and advertising presentations before the advertisement is placed in the media.

In addition, many media firms have detailed written guidelines and self-regulate advertising through an internal review process. Major network broadcast stations, for example, review all commercials prior to broadcast. Based on the review, the network stations may accept or reject the commercial or request revision. Network stations may also receive storyboards or story lines of commercials for review. If the storyboard or story line is acceptable, and if the advertiser or advertising agency submits the actual commercial based on the storyboard or story line, the commercial will be accepted for broadcast. The major television networks also have their own guidelines for advertising aimed at children. The guidelines generally restrict the use of celebrities, prohibit exhortative language (such as "Tell your mom to buy this product"), and limit the excessive use of animation in children's commercials.

Many big print media firms also have written guidelines and a formal review process. Small print media firms, however, may not have written guidelines or formal review processes.

ADVERTISING, SEXUALITY IN

In pursuit of the philosophy "sex sells," sexual images are consciously employed in advertising to promote sales of goods and services. The underlying assumption is that sexual stimuli grab the recipients' attention and reinforce the advertising message. The content of sexualized advertisements conveys images and norms relating to sexuality, gender, and gender roles. Such ads may represent or target children and adolescents, and youth may be exposed to them even when they are not targets of the ads. Research into sexual content in the media is generally focused on its problems and the dangers, but future research is needed not only on children and adolescents as victims of sexualized advertising but also as active users of the media who pay selective attention to advertising and may derive some benefits from it.

THE NATURE AND TYPES OF SEXUALIZED ADVERTISING

Sexualized representation of the opposite gender is intended to motivate heterosexual target groups to become consumers of the product advertised, thereby becoming conquerors of the opposite sex (e.g., scantily clad women may be portrayed in a car advertisement aimed at heterosexual men). In addition, each gender in a heterosexual audience is meant to be motivated to consume products advertised by sexualized representations of its own gender, effectively identifying with and imitating the attractive image (e.g., a "sexy" woman advertising perfume for women). At times, attractive models of both sexes are displayed in heterosexual interactivity to enable both of these motivation mechanisms to function within the heterosexual target groups.

Sexual representations consciously inserted into advertising are called *sexual appeals*, which means that they attempt to persuade using appeals containing sexual information. *Sexual information* is any representation that portrays or implies sexual interest, behavior, or motivation. Tom Reichert distinguishes among five types of sexual information in advertising:

1. Nudity/dress, ranging from revelation of individual parts of the body to complete nudity
2. Sexual behavior, individual or interpersonal, portrayed either openly or suggestively
3. Physical attractiveness of the model
4. Sexual referents, subtly referring to objects and events of symbolic sexual significance
5. Sexual embeds, subliminal sexual representations, either recognisable representations of objects without primary sexual significance but endowed with it by the advertising (i.e. objects in the shape of genitalia) or subliminally presented associations not recognisable but yet explicit in their sexuality.

Sexual appeals (a) may represent children and young people, (b) may target children and young people, and (c) may be perceived by children and young people whether they are looking for it or not and even though they are not part of the actual target group.

THE PREVALENCE OF SEXUAL ADVERTISEMENTS

Many studies show an increase in both the number and the explicitness of sexual depictions in the advertising of the Western world, which is reflected in how frequently sexual appeals appear and in how much freedom they are accorded.

The classic products advertised with sexual representation and provocative images (predominantly of the female body) are alcoholic beverages, cosmetic products, fashionable clothing, and automobiles. In 1936, the manufacturer of Woodbury Soap advertised the product with a photograph revealing for the first time the full naked body of a woman. Today, advertising for almost every type of product and consumer goods has a sexualized form, although the advertising message frequently lacks any direct association between the sexual appeal and the product itself. A number of enterprises (among them fashion and perfume houses such as Calvin Klein or Sisley) have been caught in the crossfire of the censors because of their explicit and provocative sexual advertising campaigns, particularly when the models were or appeared to be under age.

Several trends to be noted are related to the presentation of gender roles and stereotypes. First, there has been a decrease in representations of women as classically stereotypical housewives. Today, women are more often portrayed as independent, active people in advertisements. Second, women, particularly young women or even girls, are more frequently presented as sexual objects. Men, too, are being shown in sexual contexts more often and more provocatively. There has likewise been an increase in the depiction of homosexual eroticism in advertisements.

Magazine Advertising

Magazines contain the most frequent and most explicit but also the most artistic representations of sexuality. This is observable, in particular, in lifestyle magazines and those aimed specifically at women or at men—presumably because of the highly specific target groups. In 2003, nearly half the advertisements in American women's magazines and more than three quarters of the ads in men's magazines showed sexually explicit depictions of women. Although there have been several studies on the sexualization of female depictions in advertising (especially within traditional feminist critique of the media), little research has been done on sexualized depictions of men.

Television

There are fewer sexual depictions and allusions on television than in print advertising. In one study of American prime-time television, 12% of the models were only partially clothed, and 8% of the advertisements displayed sexual behavior. These lower percentages can be explained by the fact that television still addresses very large, heterogeneous target groups, particularly in prime-time programs for the general public. Also, many countries have established regulatory committees to monitor TV content, which have set precise limits on the amounts and types of advertising that may be shown at particular times on television. However, television programs shown at nonpeak times and targeted at specific audiences do contain markedly sexualized representations.

The Internet

Because Internet technology uses multimedia and is interactive, advertising on the Internet is much more complex than in magazines or on television. This renders detailed study and description difficult, as certain types of advertising are inaccessible to some users. It is thus possible to make only limited statements about the exact distribution of sexualized advertising on the Internet. However, it can be assumed that there is a great deal of it and that it reaches many recipients. In addition, it is quite common for sexual appeals to be related to products of a sexual nature, so the Internet is a place where sexuality is used to sell sexuality. Digital multimedia, with their potential for configuration, have led to new forms of representation of sexuality on the Web—additional animation, for instance, and stylized images of virtual people frequently far more stereotypical in appearance than real people. (For example, Jacqueline Lambiase has described ads depicting people with exaggerated secondary sexual characteristics.) However, the Internet is interactive and adaptable, such that that sexualized advertising can be suppressed and excluded from one's individual user profile. This is particularly relevant for children and adolescents, for whom it is easier to prohibit Internet material than material from other media.

Mobile Telephones

Mobile telephones are the information and communication devices with the widest international distribution. They are used intensively by adolescents and children from about the age of 9. Today's mobile phones do not act only as telephones but provide other services and products in the information field, including mobile advertisements that arrive as text or graphics

messages, video clips, or interactive games with prizes. Although it is possible for parents and guardians to observe and accompany children with relative ease when they are using television or the Internet, the use of the mobile telephone is private and not subject to direct parental observation. As in the case of online communications, there is an increasing need for technological blocking and filtering processes in the field of mobile communications because of the increasing sexual content of messages and sexualized advertisements. Likewise, young people need better training in using media.

CHILDREN AND ADOLESCENTS AS TARGET GROUPS

In 2002, according to James McNeal, American children aged 4 to 12 influenced approximately $310 billion in family spending and indirectly influenced another $340 billion; this market is also increasing by 20% every year. These numbers clearly indicate that children and adolescents form an extremely important customer target group for advertisers.

In this context, the most relevant advertising is that aimed directly at children and usually seen as part of children's TV programs or in magazines for children and adolescents. The majority of such advertising is for products such as toys, food, and especially sweets. For adolescents and young adults, the range is extended to include advertisements for fashion clothing and cosmetics. It is apparent that, in advertisements targeting children, boys are portrayed in dominant roles with clearly differentiated and active behavior. Girls, in contrast, are shown not only less often but also in a restricted range of roles. In the depiction of girls, the frequent representation of very thin, delicate female models, even in advertising for the under-12s, is striking.

Children and adolescents are also exposed to advertising that does not directly address them as consumers. Considering that the average TV consumption of an 8-to-12-year-old American child is 30 hours a week, any consideration of children and adolescents must take account of the general effects of advertising.

RESPONSES TO SEXUAL ADVERTISEMENTS

Precisely because it is such an effective signal, children and adolescents may not be sufficiently critical in their responses to sexual advertising. In this context, the concept of *coping skills* for advertising (the ability to deal with advertising in a critical manner, which can be encouraged at school as well as at home) becomes important. The two most important skills are the ability to dissociate advertisements from editorial content and the ability to understand the commercial intentions of advertising. Research has shown that both abilities are largely dependent on the cognitive development of the child or adolescent. Recent studies have demonstrated in comparatively young children a yet-earlier growth of skills in coping with advertising. However, it can be assumed that the commercial intentions of advertising are not fully grasped until adolescence. Because adolescents aspire to sexual maturity and a secure gender identity, they are particularly susceptible to representations of attractive images of "maleness" and "femaleness" in advertising and are thus encouraged to engage in uncritical consumer behavior.

Research on advertising effects has shown that sexual stimuli or erotic representations indeed can serve to intensify the attention a recipient devotes to an advertisement. However, sexual appeals have a negative influence on the memorization of brands because the strength of sexual stimuli as signals diverts the attention from the actual product. In spite or because of the strong human reaction to sexual stimuli, some people develop an antipathy toward sexualized advertising and its now-widespread occurrence. Opinion polls show that the majority of responding recipients consider that advertising has become excessively sexual. To date, there has been no specific investigation of the extent to which children and adolescents react to sexual advertising—whether positively, perhaps with curiosity, or negatively, with disgust.

A particularly difficult area is access by children and adolescents to advertisements not intended for them, such as late-night television commercials or ads on the Internet containing sexual or even pornographic material. A one-sided, stereotypical representation of girls and women is a further problem, as are images of "ideal," excessively slender girls and women (in ads for cosmetics and fashion clothing), especially as this advertising is frequently targeted at children and adolescents. The effects of such advertising on young people have barely been touched upon in research, and ethical difficulties limit the possibility of doing so. The findings from research into possible negative effects on adult attitudes, however, imply that there are grave dangers. Young people may develop

increased dissatisfaction with their own bodies, may desire to be too thin, and may have an increased probability of developing eating disorders.

Another skill required in coping with sexualized advertising is the capacity to distinguish between fact and fiction. Because children and adolescents possess only limited sexual experience, they are less able than adults to recognize whether an erotic or sexual scenario used for advertising purposes is representative of socially acceptable and everyday role models or, rather, is behavior that could induce unrealistic expectations or inappropriate social behavior. The less a person knows beforehand about a field of behavior, the greater is the probability that its depiction in the media will be taken uncritically as realistic.

Child protection considerations would dictate that the dangers of sexualized advertising should be countered, first by the regulation of production and distribution and second by appropriate education concerning the media. Studies have shown that children's coping skills vis à vis advertising indeed can be enhanced by relevant training. A useful approach is the development of appropriate media training packages, which, insofar as they relate to sexualized advertising, would also have to contain some explanation of the facts of life. Furthermore, the importance of technological progress must not be ignored. The adaptive or sorting mechanisms enabling digitized media content to be matched to the current user or target group are constantly increasing. Technical filtering systems may make it possible to protect young people from dubious media content.

POSITIVE MESSAGES IN SEXUAL ADVERTISEMENTS

If we view advertising as a reflection of the society in which it arose, the Western world's shift in values toward secularism, individualism, and liberalism are clearly recognizable, as evidenced in increasingly provocative advertising and new ways of depicting gender roles. Increasingly explicit sexual representation is contributing to sexuality's becoming less of a taboo subject in society generally, which can be seen, at least to some extent, as positive.

Examples of messages from sexualized advertising that may be beneficial and supportive to the development of children and adolescents include the idea that there is pleasure in erotic and sexual behavior; the recognition that these spheres of life can be openly shown and spoken of; the acceptance of both heterosexuality and homosexuality in the world; an understanding that heterosexual girls and women are not only sexual objects but also sexual subjects; and the recognition that attractiveness need not always coincide with stereotypical male and female icons but can also be androgynous (as, for example, girls with cropped hair and boyish clothing).

Of course, it will be subjective values that dictate which aspects of sexual appeals are viewed as positive. The question may be asked both theoretically and empirically whether and to what extent young people experience sexual advertising as a beneficial phenomenon fostering their personal development. Almost no studies to date have analyzed the nature and context of young people's interpretation of commercial sexual messages, how they discuss them in their peer groups, or how they adapt them creatively and artistically.

The fact that research into sexual content in the media is generally focused on its problems and the dangers, practically always ignoring any possible positive effects, is connected to the fact that research funding is usually easier to obtain for purposes of child protection. This suggests that future research could well concern itself with children and adolescents not only as the passive victims of sexualized advertising but—depending on their ages—as active users of the media who pay selective attention to advertising and often deal with or exploit it in their own way, constructively. Conclusions already reached should be tested further with more differentiated groups. Such differentiation could take account of both negative effects and possible constructive internalization.

ADVERTISING, VIEWER AGE AND

Children often encounter advertising and observe consumer behavior while very young. As children mature, their attitudes, beliefs, and behavioral responses toward advertising change. Developmental theory, in conjunction with marketing and advertising theory, suggests that children progress through various stages as they become full-fledged consumers in society. Research suggests that, although children are making purchases without adult supervision by the time they enter kindergarten, they do not understand the persuasive intent of advertising. Children develop as consumers throughout childhood, and, as they mature, their responses to advertising change.

INFANTS AND TODDLERS (AGES 0–2)

Research suggests that the first stage of consumer development occurs at a very young age. Infants can express their interest in particular sounds, smells, and tastes and even in television programs by 4–5 months of age. They also begin to be socialized as consumers through observation of their parents and caretakers while shopping. Scholars suggest that children begin to ask for products from parents between the ages of 18 and 24 months; however, they are still learning their roles as consumers and lack the facilities to fully comprehend the selling intent of advertising.

PRESCHOOL (AGES 3–4)

Research suggests that the second stage of consumer development begins for children as they enter the preschool years (ages 3–4). Studies indicate that some preschoolers recognize cartoon trade characters such as Mickey Mouse, although this skill increases with age. Moreover, preschoolers begin to become attached to characters they see on television. Research indicates that some preschoolers are able to distinguish commercials from TV programs, an early step in understanding advertising content; however, studies indicate that this skill is more commonly acquired around age 5.

As developing consumers, preschoolers begin to learn which stores have items that are of interest to them, and in some instances they are allowed to make purchases in the presence of their parents or caretakers. However, studies indicate that parents of preschoolers experience in-store parent-child conflict when they deny purchase requests. This may be a result of preschoolers' limited ability to be distracted from tempting products.

EARLY ELEMENTARY (AGES 5–8)

Research suggests that the third stage of consumer development begins as children enter elementary school. Children begin to make choices and purchase items. Research indicates that children make their first purchases without parental supervision between the ages of 5 and 7. Studies indicate that children become increasingly able to resist temptation and have begun to hone their negotiation skills with parents.

Research suggests that children must take a number of cognitive steps in order to understand the intent of commercials. The first step is to identify commercials and distinguish them from program content. Studies indicate that, by age 5, most children are able to distinguish commercials from television programs, but

their distinctions are very rudimentary. For example, in Scott Ward's (1972) study, young children indicated length ("commercials are shorter than programs") and placement ("before or after show") as the discriminating factors between commercials and programs.

Other steps would involve being able to discern the persuasive intent of advertising and recognize bias. Research suggests that the majority of children are able to articulate the selling intent of advertising by the third grade. As children become aware of the persuasive nature of advertising, they develop the ability to recognize bias and deception in advertising and develop skeptical or negative attitudes in regard to advertising. A consistent finding of the research indicates that, as children mature, they like commercials less and less, and they become less trustful of advertising messages. Studies indicate that children become less entertained and more irritated by commercials. This may result in the development of attitudinal defenses when they encounter advertising content. However, research suggests that these defenses may not be effective after a period of heavy exposure to advertising for toys and games, such as the pre-Christmas season.

Indeed, research suggests that heavy exposure to television advertising does have an impact on the types of items children request as Christmas presents, particularly for younger children. Much of the research regarding children's requests for products focused on their requests for toys during the Christmas season. A common method of data collection is for researchers to relate children's Christmas wish lists to their exposure to television advertising prior to Christmas. One study found that toys with the most frequently advertised brand names were the most often requested and that the number of requests for such toys could be predicted by the extent of children's exposure to the network that aired the most commercials for those brands.

LATE ELEMENTARY (AGES 9–12)

Research suggests that the fourth and final stage of consumer development begins as children progress through their elementary school years and start to evaluate products more closely. They may even begin to collect items such as dolls or baseball cards, to examine these products for quality, and to become cost conscious. Older children begin to lose interest in toys and make fewer requests for advertised products. Peer groups become increasingly important as a socializing force. Furthermore, older children tend to hold a more negative opinion of commercials, often describing them as annoying or in poor taste. This more sophisticated consumer knowledge may then be used as a cognitive defense against advertising tactics.

TEENS (AGES 13–18)

Research suggests that, during the teen years, children's knowledge of advertiser tactics closely resembles that of adults. Teens have an increased awareness of the marketplace and are more likely to recognize the techniques advertisers use for persuasion and to discern when ads are truthful or misleading. Research suggests that the more knowledge youth have about advertising and the marketplace, the more skeptical they become. This is particularly true for teens. Research indicates that factors such as well-developed marketplace knowledge, heavy television viewing, and susceptibility to peer influence enhanced skepticism in teens.

Children mature into functioning consumers throughout their childhood. Their development cognitively and socially enhances their ability to understand the persuasive intent of advertising and marketing tactics used to encourage consumer behavior. Although they still have room to grow and develop, they have experienced all aspects of consumer behavior in their childhood in some basic manner.

ADVERTISING CAMPAIGNS, PROSOCIAL

Prosocial advertising campaigns use advertising aimed at a particular audience, for a specified period of time, with the aim of achieving a specified goal that is beneficial to society. For example, the national Anti-Drug Campaign mandated by Congress runs ads aimed at teens to prevent drug use. Campaigns may be sponsored by government agencies, nonprofit organizations, commercial enterprises, or coalitions of different groups. Some well-funded campaigns pay for the advertising placements and therefore have more control over when the ads are run. Many campaigns, however, rely on donated time, and the ads run as public service announcements at the discretion of the media organization.

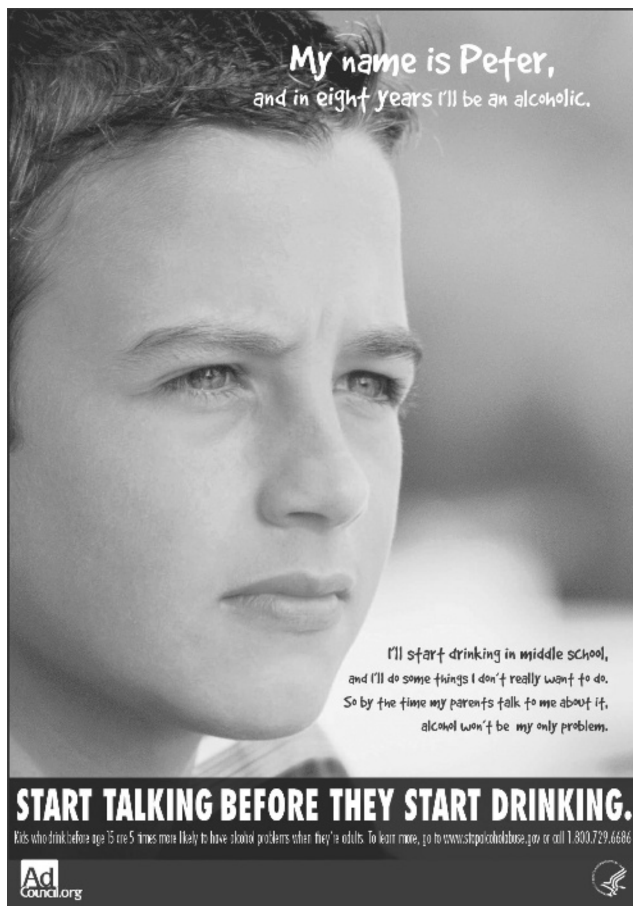
Prosocial advertising is often combined with other organized communication activities as part of a comprehensive communication and social marketing campaign. Campaigns often have greater success when advertising is used in conjunction with other mass media formats (such as news, soap operas, and testimonial programs). Infomercials often, although not always, rely on testimonials—endorsements by real people. Health messages also sometimes use testimonials to make a point. Prosocial campaigns may also use other communication strategies (e.g., using promotional materials such as caps and mugs, sponsoring contests or events, offering professional counseling or workshops in small groups, enhancing communication within communities, and advocating to change policies and alter environments to be more conducive to the desired behavior). For example, a nutrition campaign may advertise healthy foods and also advocate for the reduction of vending machines with unhealthy foods in schools.

Prosocial ad campaigns aimed at large populations of children and adolescents can affect large numbers of young people, although the percentage of the population affected is typically less than 10%. Campaigns promoting a new behavior are more effective than campaigns aiming to prevent or eliminate a negative behavior, and behaviors that can be performed once or a few times are easier to promote than behaviors that need to be repeated often. Youth substance abuse campaigns seem to have about the same effects as substance abuse interventions in schools. Alcohol use reduction and smoking prevention campaigns have a greater impact than campaigns designed to reduce or prevent illegal drug use.

Several theories are used to design better campaigns. Analysis based on developmental, behavior change, and communication theories can help to do several things: (1) identify the persuasive strategy to be used in the campaign (such as whether to emphasize certain pieces of information, risks and other motivational factors, peer norms, types of behaviors, and behavioral skills); (2) select the media and other channels to use in the campaign and determine the timing and frequency of communication; and (3) design the messages. Theory can also guide the selection of young people to target, using criteria such as current behaviors, actual and perceived risk, age at which risky behaviors begin, current knowledge and beliefs, and communication patterns. Theories that are commonly applied to campaigns include the theory of planned behavior, the information-motivation-behavioral skills model, social cognitive theory, information processing theory, and the health belief model.

It is important to carefully define the target audience(s) for the campaign, including their developmental level, to design effective messages and select the most appropriate media and other channels. For example, campaigns aimed at Mexican American teens can be designed to be sensitive to cultural beliefs and communication patterns, abilities, and preferences. Sometimes, campaigns that strive to impact youth also target parents or other people influential in children's lives in order to encourage them to perform a particular behavior on behalf of their children (e.g., bringing children to a clinic or a doctor for immunizations or to reinforce ads directed at kids (e.g., campaigns to increase bike helmet usage have asked coaches to talk to their teams).

To have greater impact, campaigns should aim to maximize the percentage of the target audience that is exposed to the campaign, and they should maintain communication over time. Ad campaigns are more successful when they run an adequate number of ads, use different versions of ads to prevent burnout, use ads that attract attention but are not so complicated that they cannot be remembered, are timed to expose



The "Start Talking Before They Start Drinking" ad campaign was launched in November 2005 and encourages parents to help prevent underage drinking by discussing this issue with their children early and often. These public service announcements (PSAs), developed in collaboration with the Advertising Council, have been distributed through television, radio, and print media, and town hall meetings have been held to reinforce the messages.

young people to the ads when they are more receptive to them, place the ads in a variety of media so that more targeted young people will see them, and use novel approaches.

Emphasizing information that is new to the target group is better than repeating ideas the audience already knows, and information that is positive usually fares better than a focus on only negative consequences of bad behavior. Ideally, all messages that the target groups see on the topic should be consistent with the campaign. Campaigns are also more successful if messages about the enforcement of policies designed to limit the behavior, such as underage purchasing of alcohol or cigarettes, are coupled with enforcement activities by authorities. Effective campaigns also avoid messages that youth would see as "preachy."

The first step in designing a campaign is to conduct research. It is particularly important to understand the desires, constraints, resources, knowledge, beliefs, communication preferences, influential people, current behaviors, and potential for change among the target audiences; the resources available to the sponsoring organization; and the social, political, economic, and legal context of the campaign. When organizations have neither the time nor the resources to conduct extensive research, it is worthwhile to locate an evaluated campaign that has been shown to be effective with a similar target audience and adapt it. The second step in campaign design is to create a communication plan, including specification of the goals of the campaign, target groups, advertising outlets, and persuasive strategy to be used by the ads. Next, the management plan needs to spell out the personnel and resources that will be used and the timetable for all campaign activities, as well as the approach to integration with other organizations and events with similar goals. The fourth step is to develop and pretest the advertisements, prepare any other campaign media messages, and train any people who will have direct contact with the target audience as part of the campaign. Then, the campaign can be implemented. Monitoring should also be in place to track the campaign and readjust the plan as needed. The final step in a campaign is to evaluate the impact of the campaign to provide feedback to the staff and sponsors for the current and future campaigns.

ADVERTISING ON CHILDREN'S PROGRAMS

Children are increasingly exposed to advertising from a wide range of sources, including billboards and point-of-purchase advertisements, product placements in movies and video games, pop-up ads on Internet sites, and both direct and indirect advertising in schools. For children under the age of 12, however, television is still their primary source of exposure to advertising. The average child sees more than 40,000 TV commercials each year, and television is still the main venue marketers use to target children under the age of 12.

Children's exposure to advertising on television does not occur only during children's programs. Research shows that even young children are typically exposed to a wide range of television programs (including situation comedies, news, and other adult-oriented programming that is coviewed with parents or is on while children are in the room doing other activities), and that the commercials shown during these programs are likely to attract children's attention even more than the programs themselves. With recent studies showing that more than half of American children have TV sets in their bedrooms (including more than 30% of children ages 2–7), children are also increasingly likely to view commercial messages without the benefit of adult guidance or regulation.

Nonetheless, TV commercials that are shown during programs specifically designed for children still provide the clearest picture of what advertising messages children see and how those messages affect their attitudes and behaviors. Potential for exposure to commercials during children's programs is, in fact, increasing with the proliferation of cable television stations devoted primarily or exclusively to child audiences (e.g., The Cartoon Network, The Disney Channel, Nickelodeon), nearly all of which include commercial messages. Furthermore, the trend is growing for product sponsorships featuring characters from children's TV programs (such as *SpongeBob SquarePants* or *Rugrats*) on product packaging, on clothing, and in children's meals at fast-food restaurants. This blending of program and advertising content is likely to make it even more difficult for young children to understand the persuasive intent of advertising.

CONTENT OF ADVERTISING ON CHILDREN'S TELEVISION

Historically, advertising during children's TV programs refers to programs with a target audience under the age of 12 (primarily cartoons). There are four types of nonprogram messages shown during children's television programs: (1) product commercials; (2) public service announcements (PSAs) and drop-ins (educational messages developed by the network or station, such as *Schoolhouse Rock* or *The More You Know*); (3) station identifications and promos for upcoming shows on the same station; and (4) program-commercial separators (or *bumpers*) that typically say something like, "We'll be right back after these messages." Nearly all of the research in this area has focused on product commercials and program-commercial separation; very little research has been done on children's understanding of PSAs and drop-ins, and almost none has been done on program promos.

In the 1970s and early 1980s, Saturday-morning (children's) television was often called "a vast wasteland," partly in reference to what was then perceived as a huge amount of advertising touting toys, junk food, and other unnecessary products to children. During that period, the length of product commercials dropped from an average of 60 seconds to 30 seconds, and by 1983 an hour of Saturday-morning TV contained an average of 14–15 product commercials (7–8 minutes), 5 promos (1–2 minutes), and 3–4 PSAs or drop-ins (2–3 minutes). This was actually a smaller amount of advertising than was found during most other time periods of the broadcast week; weekday daytime programs, for example, typically included about 16 minutes of nonprogram messages per hour, nearly all of which were product commercials.

Since then, both the frequency and the amount of time devoted to product commercials and promos have increased significantly on children's television, while the frequency and time devoted to PSAs and drop-ins have significantly decreased. An average hour of children's TV programming on the major networks (ABC, NBC, CBS, Fox) now contains about

35 nonprogram messages (not including the bumpers), of which about 26 are product commercials (averaging 10.2 minutes), 1 or 2 are PSAs or drop-ins (0.4 minutes), and 8 are promos (2.5 minutes). On cable stations, both the frequency and amount of time devoted to product commercials are lower, although the amount of time devoted to promos is typically higher.

The types of products advertised during children's programs have remained remarkably similar over time, with about 80% consisting of toys and games, cereals, candy and snacks, soda and other sugared beverages, and fast-food restaurants. The ratio of toy commercials to food commercials depends largely on the season of the year; in November and December, the number of toy commercials more than doubles as Christmas approaches, displacing commercials for cereals and snacks. In the past decade, there has been a significant increase in commercials for videos and video games, leisure activities, and recorded music (mostly displacing ads for toys), as well as a slight decrease in advertising for cereals and snacks, and a corresponding increase in advertising for other foods, such as macaroni and cheese, waffles, and yogurt.

Commercials shown during children's programs typically use high levels of special visual and auditory effects, including animation, bright colors, music, sound effects, dancing, and rapid pacing with visual cuts, or edits. Products are typically associated with fun and happiness, and detailed information about the product itself is rarely given. Commercials often feature children and/or animals, along with celebrities and animated characters appearing as spokespersons (such as Tony the Tiger and Ronald McDonald) designed to attract children's attention and aid in memory of the product.

REGULATION OF ADVERTISING ON CHILDREN'S TELEVISION

Only the advertising time for product commercials during children's programs is regulated; there are no regulations governing promos or PSAs. The Children's Television Act of 1990 (CTA) stipulates a limit of 10.5 minutes of advertising per hour on weekend mornings and 12 minutes per hour during other times. Prior to the 1984 deregulation of children's television by the FCC, studies showed an average of only 7–8 minutes of product advertising per hour, with another 2–3 minutes devoted to PSAs and other educational messages. After deregulation, the amount of product commercial time began to climb, whereas the time devoted to PSAs dropped to almost nothing. Although current research indicates that stations are largely complying with the advertising limits established by the CTA, the ceiling it set is significantly higher than the commercial time actually shown in the 1970s and early 1980s, and the time devoted to promos may account for an additional 3 or 4 minutes per hour on some stations.

The inclusion of program-commercial separators (bumpers) during children's TV programs is mandated by the FCC to help alert children to the difference between programs and commercials, although there is no specific requirement for their verbal or visual content. In recent years, the bumpers on some stations have been indistinguishable from station IDs or have even included verbal warnings such as, "Don't you dare change that channel" or "Walking away from your TV set gives you pimples." Research has consistently shown children are not able to distinguish between program and commercial content until the age of 4 or 5, and they do not typically understand the persuasive intent of commercials and the need to view claims and portrayals in them with skepticism until ages 8 or 9. The bumpers do not serve the purpose for which they were intended (i.e., to alert children that commercial content is different from program content and therefore should be viewed differently), and the more recent variations are likely to confuse children even further.

Commercials shown during children's TV programs also frequently contain disclaimers (e.g., "some assembly required," "batteries not included") or other special features (like the shot of a "complete" or "balanced" breakfast used in cereal commercials, in which the box of cereal is the most prominent feature). These disclaimers are often spoken very quickly or written in small letters on the screen, and they may contain wording that is often confusing or misleading for children.

EFFECTS OF ADVERTISING DURING CHILDREN'S TV PROGRAMS

The effects of advertisements on children are generally considered to be one of two types: intended effects (related to increasing positive attitudes about the product, desire for it, and requests or purchases of it), and unintended effects (related to such things as increased parent-child conflict, poor eating habits, illegal alcohol and tobacco use, etc.). The research on intended effects

show that advertisements are remarkably successful; until at least the age of 7 or 8, children enjoy watching commercials, remember them, typically form positive attitudes toward the products, and make frequent requests for purchase. Young children are especially susceptible to these advertising claims because of their more limited capacity to comprehend persuasive intent. Unintended effects are also well documented, especially those related to parent-child arguments over requests for toys and candy and the growing obesity epidemic in the United States, which is believed to be due, in part, to the persuasive appeals for high-sugar and high-fat foods that populate commercials on children's television. However, although there are increasing and well-documented concerns about the effects of tobacco and alcohol advertising on children, those products are virtually never advertised during children's TV programs.

ADVERTISING COUNCIL, THE

The Advertising Council, or the Ad Council, as it is more commonly known, is a private, nonprofit organization best known for its public service announcements aimed at raising awareness of and provoking action on public issues. Formed in 1941 in response to World War II, the Ad Council has taken on many major issues over the years.

Each year, the group selects 40 issues to address through communication programs that reach out to Americans through a variety of media outlets. Campaigns created by the Ad Council must be noncommercial, nondenominational, and nonpolitical. Further, campaigns must be significant, national in scope. and applicable to all Americans. The campaigns are developed free by top advertising agencies, and they are seen by millions through donated media time and space. Many of these campaigns target children's issues, and in 1995 the group made a 10-year commitment to campaigns that speak to America's children, calling it "Commitment 2000." A majority (80%) of the Ad Council's efforts are now dedicated to helping children.

Some of the Ad Council's most memorable campaigns are now icons for millions of Americans, their slogans easily recognizable. In 1944, Smokey the Bear emerged with the slogan "Only you can prevent forest fires." The campaign significantly reduced the acreage lost each year to forest fires. McGruff the Crime Dog surfaced in 1979 and continues to teach children and adults to "take a bite out of crime," asking everyone to take an active role in crime prevention. The Ad Council's campaign for the United Negro College Fund has raised almost $2 billion since 1972 with its "A mind is a terrible thing to waste" campaign. The fund has helped more than 300,000 minority students go to college. And the Crash Test Dummies, introduced in 1985, have significantly increased seat belt usage in the United States. Current child-related issues include adoption, after-school program participation, arts education, safety belt and booster seat education, breastfeeding awareness, bullying prevention, child asthma attack prevention, childhood cancer, drug prevention, early childhood development, high school dropout prevention, math and science for girls, mentoring, modeling nonviolent behavior, parental involvement in schools, secondhand smoke and kids, youth civic engagement, and youth volunteerism, among others.

In addition to its public service campaigns, the Ad Council also conducts research. In the late 1990s, the group released two studies tracking adults' attitudes toward children. In 2000, it released a manual to help nonprofit organizations interest young people in community service. The publication, *Engaging the Next Generation: How Nonprofits Can Reach Young Adults,* was produced in cooperation with two of its partners, the Pew Charitable Trust and MTV. And in 2004, the Ad Council released a report using results of a public opinion poll to make recommendations on how to engage the public to act on the behalf of children (*Turning Point: Engaging the Public on Behalf of Children*).

ADVERTISING IN GIRLS' MAGAZINES

Millions of girls around the world rely on magazines targeted to them for information about the newest fashion and makeup trends, updates on their favorite celebrities, and advice about relationships. In the United States, for example, the combined circulations of the top five teen-targeted magazines totaled more than 6 million during July 2005, with the most popular teen magazine, *Seventeen,* boasting a monthly circulation of 2,108,292, according to *Mediaweek.com's* Magazine Monitor. Research indicates that advertising in these magazines has an impact on teen girls' body images and may also affect their attitudes toward materialism and their overall satisfaction with their lives.

Despite some declines in teen magazine circulation figures and the closures of two popular teen magazines in 2004 and 2005, these magazines continue to play a significant role in the lives of adolescent and preadolescent girls. Researchers have found that girls who regularly read teen magazines use them to help learn how to be "feminine" and how to attract and maintain relationships with boys, although the magazines influence white girls' perceptions of beauty more than they do black girls' beliefs. Other studies have shown that girls believe that teen magazines tell girls that they should strive to be "perfect" like the models who appear in the magazines and that the ideal, which includes having a thin, fit body, perfect eyes, and perfect teeth, is attainable if the reader works hard enough and buys the correct products.

Survey research also has documented the impact of magazines on teenage girls' beliefs about what constitutes the ideal female form and on their satisfaction—and dissatisfaction—with their own figures. The results of a *Teen People* magazine survey, released in August 2005, showed that more than 50% of the 1,500 teenage girls surveyed believed they weighed too much; fewer than one third of white and Hispanic girls and 51% of black girls said they were totally satisfied with their bodies. Nearly 60% of the 13-to-18-year-old girls surveyed said comparing themselves to the models they see in the media, including magazines, makes them feel more insecure about their own bodies.

Studies specifically focusing on the content of advertising in teen girls' magazines have been surprisingly scarce. One study of advertising images in *Seventeen* magazines published in the United States and Japan revealed that two thirds of the ads in the American magazine issues were for cosmetics, including skin and hair care products, fragrances, and makeup. Clothing ads came in a distant second, accounting for about 11% of the ads. The researchers concluded that girls in the Japanese magazine were presented as playful, happy, and girlish, while ads in the American magazine frequently portrayed girls as independent, determined, and defiant. In contrast, another study of the photographs of females in *Seventeen* ads from 2003 revealed that more than half the ads showed women as subordinate to men, and nearly one in four ads included signifiers of "sexuality as power." Researchers examining Australian magazines targeted at teen girls have found that

advertising images of girls are dominated by thin, attractive girls; girls who are athletic-looking are presented far less often and heavy girls almost never. Thus, advertising in the magazines aimed at teen girl readers emphasizes the image girls present to the world as most important. Girls' abilities, interests, and accomplishments—other than those related to their appearance—are presented, at best, as of secondary importance to their value as individuals.

CROSSOVER READERSHIP

A careful search of the published literature revealed no studies focused solely on the effects of girls' exposure to advertising in teen-targeted magazines. However, it is important to note that millions of adolescent girls—including readers and nonreaders of teen-focused magazines—are exposed daily to the advertising content of magazines aimed primarily at adults. Indeed, several recent entries into the teen magazine market—including *Teen People, CosmoGirl, Elle Girl,* and *Teen Vogue*—have been introduced to capitalize on teens' interest in and readership of the adult versions of each magazine (*People, Cosmopolitan, Elle,* and *Vogue*). According to research by the Simmons Market Research Bureau, nearly one quarter of the readership of women's magazines are 12-to-17-year-olds, as are 18% of the readers of fashion magazines. Given adolescent girls' frequent exposure to these adult magazines, and given that at least some of the products and models appearing in women's magazines also may be featured in teen magazine advertising, it is relevant to examine what researchers have discovered about the effects of exposure to the ads in magazines for adult women. The research generally has focused on three major areas: the effects on body image and weight and shape control behaviors, the effects of exposure to alcohol advertising, and the influence of cigarette advertising.

Numerous studies have revealed links between exposure to women's fashion and beauty magazines and disordered eating attitudes and behaviors. In one study, for instance, Renée Botta (2003) concluded that there was a marginal correlation between reading fashion magazines and bulimic behaviors among girls; however, reading health and fitness magazines was related to higher levels of bulimic and anorexic behaviors and an increased drive for thinness. Among Botta's study participants, women who more often compared themselves to the images of women published in magazines were more likely to engage in anorexic and bulimic behaviors and reported a higher drive for thinness and lower body satisfaction. Other researchers have found that reading beauty and fashion magazines was significantly related to high school girls' dieting behaviors, even after anxiety about weight and exercise frequency were considered. Although images of thin women appear in numerous media channels, magazine images seem to produce the strongest effects on girls' beliefs about the importance of thinness and the behaviors they engage in to try to achieve the media-depicted ideal. For instance, recent research by Kristen Harrison (2001) demonstrated that exposure to "thin-ideal" television programming was not correlated with eating disorder symptoms among teenage girls. However, exposure to thin-ideal magazines was associated with anorexia among girls in 6th, 9th, and 12th grades and with bulimia among girls in the two older age groups. In addition, exposure to sports magazines—in which models typically are lean *and* muscular—was associated with body dissatisfaction among 12th-grade girls.

Much of the research on the connections between magazine exposure and girls' body dissatisfaction and eating disorders has demonstrated that magazine reading is linked to negative body attitudes and sometimes to unhealthy behaviors, but most have not been able to demonstrate that exposure to magazine images *causes* girls to be dissatisfied with their bodies or to engage in unhealthy weight control behaviors. However, at least one experimental study conducted in Australia lends support to the idea that exposure to magazine advertising increases girls' concerns about their weight. In this study, female college undergraduates viewed magazine advertisements showing the full image of a woman, a woman's body part only, or a product image. After viewing images portraying the thin ideal for women, the students reported more dissatisfaction with their own bodies and more negative moods. The researchers pointed out that their findings were particularly disturbing given that the undergraduates had been exposed to these thin images for only a brief period—about 10 minutes—suggesting that girls who regularly read the typical women's fashion or fitness magazines may be setting themselves up for negative moods, body dissatisfaction, and the feeling that they *must* try to achieve the image of perfection they see in the magazine ads. This effect may not be limited only to girls who are already concerned about their weight; Harrison's study demonstrated that the links between magazine exposure and eating disorder

symptoms held even for girls who reported no prior interest in body improvement content.

While the majority of the research has linked magazine images with girls' weight control concerns and behaviors, more recent research suggests that viewing magazine models also may influence girls' satisfaction with their breast size. Experimental, survey, and qualitative research published in the past few years has demonstrated that media depictions of thin yet busty women may influence girls' satisfaction with the size of their breasts. Because breast tissue is primarily fat, girls who diet or exercise to achieve the media ideal of thinness are simultaneously working against their desire for larger breasts. In other words, for most girls the only way to achieve the media ideal of a thin waist and hips, coupled with larger breasts, is through breast augmentation surgery. Although 75% of the girls in the *Teen People* survey said they never would consider having plastic surgery, the statistics indicate that the number of teenage girls getting breast implants has been increasing rapidly. The American Society for Aesthetic Plastic Surgery reported that, between 2002 and 2003, the number of breast implant surgeries among girls 18 and younger nearly tripled, from 3,872 to 11,326.

However, the research on the effects of images of women in magazine ads on girls is not totally consistent. A few studies have provided evidence that sociocultural influences, including the feedback parents and friends give girls about their body shape and weight, are far more important than any media influences. Girls whose parents and friends encourage them to lose weight and to strive for thinness may be far more at risk than those whose parents and friends urge them to accept their bodies as they are, regardless of how much time girls spend looking at magazine advertisements. Other research has suggested that what girls *do* when they are looking at magazine advertising images of females may be more important than how many images girls view or how often they are exposed to those images. Girls who compare their own bodies to those of the models they see in advertising seem to be more at risk, whereas girls who can view the ads without making these comparisons seem less likely to be affected by the ads.

ALCOHOL ADS

The American magazines targeted to teenage girls do not carry alcohol advertisements. This results from two factors: Teen-oriented magazines generally do not accept alcohol advertising, and all three of the major alcohol industry associations voluntarily prohibit their members from advertising in media for which the majority of the audience is younger than the legal drinking age. However, as noted in the previous section, crossover readership of magazines means that teenage girls may be regularly exposed to alcohol advertising through their readership of magazines targeted to an older audience.

This exposure is quite common, according to the Center on Alcohol Marketing and Youth. The Center's research has shown that, in 98 magazines they studied, nearly a third of all alcohol advertising dollars spent in magazines went to magazines at least one of every four readers of which was a teenager. Similarly, a study of magazine alcohol ads from 1997–2001 showed that the number of alcohol ads increased with the number of adolescent readers of the magazine. For each additional million teenage readers (ages 12–17) of a magazine, the number of beer ads was 1.6 times higher, and the number of distilled liquor ads was 1.3 times higher. Exposure to alcohol advertising does have an effect, according to much of the research on the subject. Teen girls who are exposed to more alcohol ads and who pay more attention to those ads are more likely to report drinking or intending to drink alcoholic beverages.

Similarly, although the tobacco industry does not advertise in magazines targeted specifically to teenagers, research indicates that tobacco advertising reaches a significant percentage of 12-to-17-year-olds through their reading of adult-targeted consumer magazines.

MATERIALISTIC ATTITUDES

One final area of concern about the effects of advertising in teen magazines revolves around how these ads may influence teens' attitudes toward materialism, rather than their adoption of specific unhealthy behaviors such as disordered eating, alcohol abuse, or smoking. Some researchers have suggested that being surrounded by a culture in which teens are encourage to buy more and more products, especially brand-name products, makes teens more self-conscious, more concerned about external appearances, and generally less satisfied and happy with their lives.

AFRICAN AMERICANS, MEDIA EFFECTS ON

Today, African American children and adolescents, like their peers of other ethnic groups, are born into a world of mass media that is in a state of constant change and dynamic motion. Although television remains the ubiquitous medium for information and entertainment, the presence of the computer, online capabilities, video games, and other electronic and print marvels continue to compete for the time and attention of these developing children and youth. The present and emerging forms of media also bring with them content and features that can challenge many of the views, attitudes, and social values of the family and other traditional agents of socialization. Thus, researchers, parent groups, educators, and others interested in child growth and development issues need to continue to explore ways to better understand the new social and psychological effects of various types of media on these children and adolescents.

Researchers and groups interested in the psychosocial effects of mass media on African American children and adolescents face the special challenge of understanding them within the context of the longstanding paradoxical relationships between African Americans and media in the United States. The images, portrayals, and coverage of African American life and culture by some media of the past and present were molded years ago, when the country decided to develop what some historians have called the "peculiar institution" of slavery. Jannette L. Dates and William Barlow have suggested that the reemerging 20th-century mass media industries of film, radio, advertising, news, records, and, later, television grew out of those early periods and contained many images based on the prevailing 19th-century stereotypes. Paradoxically, however, it was the later forms of radio, television, newspapers, and other mass media that provided some of the pressure for the passage of the Civil Rights Act of 1964 and the Voting Rights Act of 1965.

PSYCHOSOCIAL DEVELOPMENT AND MASS MEDIA

It is against this backdrop of past and present sociopolitical events in this country and the agenda-setting role the media have played in them that African American children and adolescents have had to manage the natural processes related to their physical and psychosocial development. These stages of development must also be experienced concurrently with becoming a part of a vibrant mass media culture. The Aspen Institute Forum noted that the dynamic nature of this mass media culture is represented by broadcast and cable television, radio, newspapers, books, magazines, recorded music, advertising, computers, video games, Internet services, World Wide Websites, direct broadcast satellite services, and other emerging forms of mass communication. The impact of this mass media culture on the lives of African American children and adolescents cannot be overemphasized, because with the press of a button or the turn of a knob, they offer a vast array of entertaining, informational, and accumulated cross-cultural experiences that provide positive and negative life lessons, challenge family-based values, and influence personal identity.

A number of these important and interrelated life lessons and values emerge when we look at the accumulated experiences acquired from the mass media by African American children. It is, however, the construct of ethnic identity that is frequently embedded and discussed in the literature. Ethnic identity is a complex construct, yet authorities generally refer to it as having components of self-identification as a member of a group, attitudes about oneself as a group member, and ethnic beliefs and attachments. Significantly, this concept of ethnic identity and the effects of the mass media on African American children and adolescents become more salient when one considers studies linking the roles of television and other media in creating cultural stereotypes with the shaping of some negative dimensions of self-esteem. For example, some reports estimate that there are as many as 2,000 Internet sites offering games and other content that preach racial hatred aimed at children. Conversely, television and other forms of print and electronic media have been found to be excellent tools for teaching positive cross-cultural beliefs and values related to pride in various ethnic groups as a part of the socialization process.

It is frequently within the components of the socialization process that African American children and adolescents are most likely to learn from family members, to realize through media images and content, or to simply have real-world social experiences that will communicate to them what it means to be a person of color in the United States. Charles L. White noted that this ethnic or racial awareness does not come all at once but falls into place gradually during middle childhood, preadolescence, and early adolescence. The types of reactions, positive or negative, that children have to the awareness of their racially based experiences are important to mass media effects studies. The reactions of the children and adolescents are important because of the need to know how they construct and process the psychosocial meanings from the media experiences.

EFFECTS OF MASS MEDIA

The bulk of the research literature suggests that, based on the levels of usage, African American children and adolescents are highly attracted to television and some related screen media. Television and other forms of media bring with them attractive child, teenage, and adult models. Psychologists and other specialists know from social cognitive theory that children and young people learn from attractive models and the formal features of sound, lighting, and camera angles as they use stored information or schemata that guide and help them to understand the media content. Both schema theory and its interrelationship to the construct of modeling become important in studying various forms of media and their roles in the lives of African American children and adolescents. Paul Eggen and Don Kauchak define a schema as a type of script that plays a role in guiding the behavior of an individual. Drawing further on their work, we can say that models are likely to be most influential on African American children and adolescents who perceive them as being similar to themselves, as competent, and as having high status, as so many people in the media are seen to be.

The types of behavioral understandings and relationships that African American children and adolescents will construct from the media will partly depend on a complicated set of personal and family conditions. Research developed by the Kaiser Family Foundation identified three conditions in the home environment that can play a role in the media behavior of children and their peers. These conditions are (1) the kinds of media in a household to which children have access; (2) the availability of a particular medium or multiple forms of media; and (3) the family's media norms—their general orientation toward media and the extent to which the family enforces rules such as those related to television viewing or surfing the Web. It is fair to argue that the conditions described in this research from the Kaiser Foundation would be consistent for the homes of African American children and adolescents. This assumption is supported by some other findings in this same study suggesting that African American children watch all screen media combined more than an hour longer per day than Hispanic children do, and more than two hours longer than white children.

In addition, findings from a number of researchers suggest that television and other media can have maximal effects on African American and other children if the information and values involve content that evokes an emotional set of responses; if the information and values are age appropriate for the viewers and linked to their needs and interests; and if family members, caregivers, and friends do not provide children with a set of guidelines and standards for judging media content. Some additional observations related to

African American children and adolescents are that they seem to prefer programs that feature black characters; they seem to rely on the media for information related to how to talk, dress, and related social behaviors; and that adolescents seem to be interested in the media to learn about careers and various types of work experiences. The preference by some of these children and adolescents for characters with similar racial characteristics can be driven, in part, by their emerging level of ethnic identity. Some of their other behaviors are also motivated by their natural desire to practice or imitate what they see and hear in various types of media, as well as their desire to follow behaviors most acceptable to the peer group.

It is clear that the effects of various types of media are influenced, to a large degree, by each person's psychosocial makeup, socioeconomic status, age, ethnic identity, and a variety of other factors. Researchers, educators, and others interested in growth and development issues will need to continue to employ rigorous multidisciplinary and cross-cultural models or paradigms to better understand the effects of mass media on African American children and adolescents, who live in an ever-changing multimedia world.

AFRICAN AMERICANS, MEDIA IMAGES OF

Today, television is the world's primary storyteller; it tells most of the stories to most of the people most of the time. Children of the world are now born into homes in which, for the first time in human history, centralized commercial institutions, rather than parents, church, or school, tell most of the stories. Television shows and tells us about life—people, places, striving, power, and fate. It tells us who is good and who is bad, who wins and who loses, what works and what doesn't, and what it means to be a man or a women or a member of particular racial group. Moreover, knowledge about minority groups, for some people, is largely dependent on what they see on television. Images of African Americans on prime-time television shows are important to our understanding of the impact of media images on children and adolescents, given that young people, especially teenagers, do much of their viewing during these hours.

The way minority groups, including African Americans, are portrayed on television has been a consistent and important focus of research on television. Some of the early research was fueled by government funding. In the late 1960s, for example, the Kerner Commission, appointed by President Johnson to investigate racial disturbances in many U.S. cities, charged that these disturbances could be traced to the American mass media industry's failure to serve and adequately represent minority interests. The Kerner Commission found that the media seemed to encourage racial conflict by presenting African Americans in negative and limited ways; the commission suggested

that the industry and its regulating agencies give priority to improving coverage related to minority groups. In the mid-1970s, a study commissioned by the U.S. Commission on Civil Rights found that minorities continued to be both underrepresented and portrayed in stereotypical ways in network prime-time broadcast programs.

The research literature is filled with studies conducted during the 1970s and early 1980s examining minority images on television. Most studies found a high degree of consistency in television's demography. Many found that African Americans were generally portrayed in stereotypic roles and as less powerful and less important than whites. Some early studies found that African American characters appeared to be younger, funnier, and flashier than white characters and that these characters were poorer, jobless, or cast in jobs below the top echelons. Moreover, African American characters were rarely cast as "bad" or as villains; in fact, it seemed as though television writers went out of their way not to cast them in negative roles. Interestingly, the research also found that prime-time network series often included communication practices that do not facilitate close cooperation, intimate relationships, or deep friendships between African Americans and whites.

According to several studies of network prime-time programs conducted during the 1970s and 1980s, the percentage of African Americans on television had begun to reflect their proportion in the U.S. population. Similarly, Nancy Signorielli (1985), in an analysis of data from 22 annual samples of prime-time network dramatic programs collected between 1969 and 1988, found that African Americans and other minority characters made up less than 15% of all characters and about 10% to 12% of characters in major roles. Today, there is an even greater degree of parity. African Americans in the prime-time programs of the mid-1990s reached a level of representation in prime-time programming that accurately reflected their numbers in the U.S. population (about 12%, according to the 2000 Census). Moreover, by the early 2000s African Americans were overrepresented in relation to their numbers in the general U.S. population. In comparison with African American and white characters, those in other minority groups, particularly Hispanics and Latina/os, Asians, and Native Americans, are nearly invisible.

Minorities, especially African Americans, are not found in diversified roles on television. In the mid-1980s, African Americans appeared most often in situation comedies and in programs whose characters were mostly African American. These trends continued in the programming of the 1990s and 2000s. African Americans are often found in situation comedies, many of which feature African American characters only and are aired on the newer, smaller, and less popular (lower-rated) networks such as UPN. African Americans in prime time thus seem to have been granted parity with their numbers in the general U.S. population only because they are typically found in programs whose characters are all minorities. Interestingly, Nancy Signorielli, Ariana Horry, and Kristin Carlton (2004) found that the programs with all or mostly all minority characters make up less than 10% of the available programming in prime time but account for more than 40% of African American characters and are typically found on only one network, UPN.

On the other hand, in analyses of the samples of broadcast programs, other minority groups are not typically found in situation comedies and are more likely to be involved in violence. For example, Hispanics and Latina/os (usually Mexican Americans and Puerto Ricans) were usually involved with gangs or barrios. Similarly, Dana Mastro and Bradley Greenberg (2000) found that 77% of Hispanic and Latina/o appearances were on crime programs. In the most recent studies, characters of other races and Hispanics are presented with more diversity than African Americans. They are not found primarily in situation comedies and are more likely than African American characters to be seen in action-adventure and drama programs. These two groups of characters are also not relegated to the mostly minority or all-minority programming and are typically found in the programs with racially mixed casts. Finally, they are more likely than African Americans to be found in programs broadcast on ABC, CBS, and NBC, rather than on UPN, which often features programs with African Americans.

White characters, on the other hand, have parity in relation to their numbers in the general U.S. population and are presented with more diversity. Although whites are also most likely to be cast in situation comedies, they are also found in action-adventure and drama programs. Yet, white characters are also somewhat isolated from characters of other races and ethnic groups. The large majority of white characters are found on programs with all-white or mostly white casts, and very few are found in programs whose casts represent different races. Moreover, the majority of

white characters are found on the "big three" networks—ABC, CBS, and NBC—and are rarely seen in programs broadcast on UPN.

Nancy Signorielli (2005), looking at prime-time programs broadcast between 1997 and 2005, also found considerable differences by sex. African American men are equally likely to be found in both the racially diverse and mostly minority programs, whereas African American women are almost twice as likely to be found in mostly minority programs compared to racially diverse programs. Similarly, white men and white women appear most frequently on the mostly white programs, followed by the all-white programs. Only about a fifth of the white men and white women are found in racially diverse programs, and they make only token appearances in the mostly minority programs. Consequently, on broadcast network television there is a high level of isolation by race, with African American women being particularly segregated.

The types and prestige of occupations found in network prime-time broadcast programs differ by both sex and level of character diversity in the programs. Women in the programs with mostly minority or all-white casts often do not have jobs, their jobs are not made known to viewers, or these characters are depicted as not working outside the home. This image is particularly telling for the African American women in the mostly minority programs, in which 6 out of 10 are not seen working outside the home.

Numerous analyses of occupations on television have shown that characters who are professionals or in law enforcement are overrepresented, but those in white-collar or blue-collar jobs are underrepresented. Interestingly, Nancy Signorielli (2005) found similar patterns in all programs except those populated mostly by minority characters. Among the men, those with jobs in the professions appear in all types of programs. Law enforcement jobs also are seen in the programs with mostly white characters and racially diverse characters but infrequently in the programs with all white and mostly minority characters. Among the women, on the other hand, those in the racially diverse programs, followed by those in the mostly white programs, are most likely to be professionals. The smallest proportion of women cast as professionals is found in the mostly minority and the all-white programs. Moreover, African American women in the mostly minority programs are the group least likely to be cast as professionals.

Occupational prestige also differentiates between African American and white characters. On television, relatively few jobs are categorized as nonprestigious, and most are either neutral in prestige or prestigious. Levels of occupational prestige, the racial makeup of the programs, and the sex of the characters are interrelated. Women, particularly African American women in the mostly minority programs, have the least diversity and prestige in terms of the jobs in which they are seen. Similarly, white women in the programs with all-white casts are the least diverse in terms of the types of jobs in which they are found. Men's occupations, on the other hand, are equally diverse no matter what type of program they are found in, except for the lack of law enforcement–related jobs in the mostly minority programs (which typically are situation comedies).

Overall, our knowledge of how African Americans are seen on television indicates that prime-time programs typically lack racial diversity. African American characters are typically found in the small group of programs whose characters all are African Americans, and African American women, particularly those in these programs, tend to have the least diversified types of jobs. Most of these programs are broadcast on UPN, a network that, although typically garnering lower ratings than the older networks, is a popular viewing choice of African Americans, particularly African American adolescents. Finally, although there is little information about how African Americans are presented on Black Entertainment Television (BET), a cable channel oriented toward African Americans, Jones (1990) found that younger African American cable subscribers often watched BET and were typically more satisfied with these programs compared to African American–oriented broadcast programming.

MINORITIES IN MUSIC VIDEOS AND THE MOVIES

Music videos are a genre particularly popular with children and adolescents. Videos, because they are so compressed, often rely upon stereotypes and cultural shortcuts. Early studies of music videos found that concept videos (those that tell a story) had primarily white and male characters and very often were gender stereotyped. Violence appeared frequently, and white males typically were the aggressors. Soul, hip hop, and rap music videos appear most often on BET, the venue

in which we find most black performers, male and female. Many of these images, however, are hypersexualized, with highly gender-stereotypical images of both men and women. These videos, particularly hip hop and rap, show more scenes with sex, alcohol, smoking, violence, guns, and profanity than rock videos and typically show black males exhibiting these behaviors. African American women usually appear in hip hop videos as dancers and models, but recently some women have appeared in these videos as the performers. At the same time, hip hop and rap videos are often criticized because of the negative image they present of African American women, particularly their sexuality. In addition, whereas the African American culture is more accepting of diverse body types, music videos, including hip hop and rap, are much more likely to show African American women with thin and sexy bodies. Finally, movies, like other media, have fewer minorities, who are often portrayed in traditional, stereotyped, and sometimes subservient roles. In addition, many films popular with teens often have scenes conveying a distorted sense of romance as well as scenes depicting explicit sexual behaviors. These films, on the other hand, rarely mention contraception or other risks of sexual intercourse.

AFRICAN AMERICANS, MEDIA USE BY

Over the past four decades, studies examining media use among individual ethnic groups have uncovered four prominent trends in media use by African Americans. African Americans consume more media than viewers of other ethnic backgrounds, have a more positive attitude toward media, and prefer media aimed at and featuring African Americans. There is also evidence that the degree of ethnic identification among African Americans affects their media usage.

MEDIA CONSUMPTION

One consistent finding is that African American children and adolescents consume more media than whites and than members of other ethnic minority groups, often averaging 1–2 hours more per day. In a 2005 national survey of more than 2,000 youth aged 8 to 18, Donald Roberts, Ulla Foehr, and Vickie Rideout found that black youth are substantially more likely to use screen media (TV, videos, and DVDs) on any given day and spend more daily time with screen media (5:53) than either Latina/o (4:37) or white (3:47) youth. These differences appeared overall and at each level of parental education and income. Indeed, the physical environments of the black respondents were saturated with electronic media, with black youth more likely than white youth to report having each of the following in their bedrooms: televisions, DVRs, cable or satellite, subscriptions to premium TV channels, and video game consoles. Others have found that, for a large segment of black children, media use is a

near constant. In a 2004 survey of middle school students conducted by Jane Brown and Carol Pardun, 39% of black students reported watching television "almost all of the time I'm not in school," as compared to 16% of white students.

These heavy usage rates apply across nearly all media genres except computers. For example, in a 1988 survey of children in grades 2, 4, and 7, Betsy Blosser found that, in comparison to whites, black children spent more time watching TV, listening to the radio, playing video games, going to the movies, and reading books. These patterns also start quite early. In a 2005 survey of 1,065 parents of children aged 6 months to 6 years, Sowmya Anand and Jon Krosnick found that black toddlers and preschoolers spent more time watching television and reading than their white counterparts.

ATTITUDES TOWARD THE MEDIA

A second consistent finding is that black children and adolescents appear to hold a more positive orientation to the media than do whites. Evidence indicates that African Americans hold more favorable attitudes toward TV and advertising than do whites, report higher levels of satisfaction with TV, and are more likely to report using TV for information and as a source of guidance and learning. For example, in his 1972 survey of black and white children and teens, Bradley Greenberg found that black students were more likely than white students to agree that TV taught them most of what they know about jobs and about how women and men solve problems, how husbands and wives interact, and how teenagers act. Evidence also suggests that black children attribute greater realism to TV portrayals, regardless of a character's race, than do children of other ethnic groups.

PREFERENCE FOR BLACK-ORIENTED MEDIA AND ARTISTS

A third consistent finding is that African Americans express strong preferences for black-oriented media and artists. Despite the small number of black comedies and dramas on television, black children watch them frequently, tend to judge black characters favorably, and often identify more strongly with the content and portrayals than they do with white-oriented content. Findings published by Osei Appiah in 2002 also indicate that black students are more attentive to black characters, perceive them more favorably and more similarly to self, and recall more information about them in comparison to white models. This preference for black-oriented media is also seen in music genre choices. Although rap/hip hop emerged as the most popular genres with all adolescents in the 2005 survey led by Donald Roberts, blacks were still significantly more likely than youth in other ethnic groups to listen to it. Approximately 81% of blacks, versus 60% of whites and 70% of Latina/os, reported listening to this genre. Furthermore, the top genres consumed by black youth were all heavily influenced by African American performers and culture: rhythm and blues/soul (33%), reggae (24%), and gospel (19%). Given these preferences, the high rates of media use among black youth are less surprising and often reflect their consumption of mainstream *and* black-oriented media.

Indeed, it has often been argued that black and white children inhabit somewhat different media worlds. Supporting this notion are the 2004 findings of Jane Brown and Carol Pardun, who investigated viewing choices among 2,942 black and white middle school students. Participants were asked to indicate which of 140 current programs they watched regularly. Findings indicated that black girls and boys showed a clear preference for programs featuring black characters. *Each* of the top 10 programs watched by the largest proportion of black teens in the sample featured predominantly black casts. At the same time, few whites (16% or less) watched any of the top shows favored by black teens.

IMPACT OF ETHNIC IDENTIFICATION

A fourth set of findings has focused on demographic correlates of black media use, highlighting the role of ethnic identification. Here, the expectation is that black youth who identify more strongly as such should engage in different media use patterns than black youth whose ethnic identities are less secure, positive, or salient. Most evidence supports these expectations, although some null findings have emerged. Across several studies, findings have indicated that, in comparison to those with a weaker ethnic identity, black college students and adults who identify more strongly as African American or with African American culture also identify more strongly with black actors in advertising, spend more time browsing and respond more favorably to black-oriented websites, and tend to be more critical of the media, in general. For example, in their interviews

with 300 black adults, Richard Allen and William Bielby (1979) reported that blacks with a high level of racial group identity watched less TV and were more critical of black sitcoms. However, in her 1980 research study of black high school students, Jannette Dates found *no* correlation between students' racial attitudes and their evaluations of black TV characters. Their racial attitudes were not consistently associated with their evaluations, perceived reality, or identification with popular black and white characters. The way in which ethnic identity is assessed and defined may play an important role in these divergent findings.

A second demographic factor found to influence black media use is education. Here, being a more educated adult or having a more educated head of household has been associated with lower levels of television viewing. For example, in their 1979 study, Richard Allen and William Bielby found that better-educated black adults watched TV less overall, tended to view both majority and black-oriented public affairs programs more often, and were more critical of black-oriented programming.

DOCUMENTED MEDIA EFFECTS

Many have speculated that, of all media audiences, black youth may be especially vulnerable to television's influence because of their higher levels of consumption, positive feelings toward the medium, and greater use of TV for learning about the world. Unfortunately, however, few studies investigating media influences have used black children and adolescents as participants. As a result, findings from past research give us only rudimentary knowledge of television's effects on black children and adolescents.

Self-Concept

One group of studies has examined whether high levels of exposure to mainstream media, in which blacks are underrepresented and often negatively stereotyped, will have adverse effects on young black viewers' self-conceptions. In one of the first studies testing this notion, Carolyn Stroman (1986) examined associations between weekly hours of television viewing and the self-concepts of 102 black third through sixth graders. Findings indicated that greater TV viewing was associated with a more *positive* self-concept among girls but had no connection for boys. Later, in a 1984 study, Steven McDermott and Bradley Greenberg examined associations between self-esteem, racial self-esteem, and black fourth and fifth graders' exposure to and connections with *black-oriented* programming. Here, more frequent viewing of black programs and holding more positive attitudes toward black characters were each associated with *higher* self-esteem. In more recent work, L. Monique Ward (2004) demonstrated that greater exposure to mainstream programming and stronger identification with white characters were each associated with *lower* self-esteem among black high school students, whereas stronger identification with popular black characters was associated with *higher* self-esteem. These effects were especially consistent among students with lower levels of religiosity. Together, these findings suggest that exposure to and connections to black-oriented media may be beneficial to black youth, whereas connections to white-oriented media are less consistent and may depend on the age of the participant. Indeed, it may be likely that the self-concepts of black adolescents are particularly vulnerable because this is a time of heavy identity exploration.

Women's Body Image

As with the literature on general self-esteem, it is typically expected that frequent media exposure will be associated with a negative body image among young black women, who typically do not match the Eurocentric beauty ideals dominating the media. However, recent evidence from both empirical studies and interview data suggest that this is not necessarily the case, indicating that black women often reject these ideals as culturally irrelevant and instead relate more readily to black images and models, often in a positive manner.

For example, in a 1995 experiment with African American college students, Jalmeen Makkar and Michael Strube reported that participants high in self-esteem and African self-consciousness rated themselves as *more* attractive after exposure to images of attractive white women. In a similar experiment, Cynthia Frisby (2004) found that black female college students exposed to images in popular magazines did *not* engage in social comparison with the idealized images of Caucasian females. Exposure to these models did not affect these women's mood or self-esteem. However, when black women were exposed to idealized images of *African American* models in a follow-up study, those who were initially lower in self-esteem were later less satisfied with their own bodies.

Similar effects of viewer–race and character–race have emerged in studies examining women's regular media use at home. In a survey study published in 2000, Renee Botta found that more frequent TV viewing was associated with increased bulimic symptomatology for white teenage girls but not for black girls. For both groups, however, the more the girls idealized TV images and the more often they compared themselves and their friends to those images, the stronger was their drive to be thin and the more dissatisfied they were with their bodies. Surveying female undergraduates, Deborah Schooler and colleagues (2004) found that, among black women, more frequent viewing in high school of TV programming with predominantly black casts was associated with less body dissatisfaction, a lower drive for thinness, fewer tendencies toward bulimia, and fewer negative thoughts about the body. Few effects came from their viewing of programs with predominantly white casts. Overall, the data indicate that many black female viewers reject white beauty ideals presented by the media and compare themselves favorably to and are perhaps inspired by images of black women. For those who do idealize the white ideals, negative self-evaluations emerge as expected.

Evidence that black women may reject mainstream beauty ideals can also be seen in qualitative interviews of black and white high school girls conducted by Lisa Duke (2000) and Melissa Milkie (1999). Emerging from this work are findings that black girls are largely uninterested in teen magazines' beauty images because they conflict with African American standards of attractiveness. Instead, black girls reported enjoying the magazines for what they saw as relatively generic content on topics like social issues and entertainment. They viewed much of the beauty content as irrelevant or unrealistic and as intended specifically for white girls. As a result, the black girls did not actively admire or seek to emulate the white models but instead focused on images of black performers, athletes, or leaders, however infrequently they were depicted in the media. It appears that being outside the dominant culture gives black girls more space to critique its beauty standards.

Beliefs About Gender, Sexuality, and Violence

Because research consistently links frequent media use with aggression and with greater acceptance of stereotypical attitudes about gender and sexuality, concern has been expressed about how these links might work among African Americans. Will heavy media use among black children and adolescents produce the same (or stronger) effects than those seen among white youth because black youth are heavier media consumers? Or will heavy media use create weaker associations among black youth because of the paucity of black characters and role models to emulate? The limited existing evidence supports the first notion, finding that black youth are just as susceptible as white youth to media effects on social attitudes and behavior.

First, data from two studies indicate that more frequent viewing of sexually oriented genres, such as soap operas and music videos, is associated with increased acceptance of stereotyped notions about sexual roles and relationships among black adolescents (Walsh-Childers & Brown, 1993; Ward, Hansbrough, & Walker, 2005). Second, experimental data confirm these findings. In a 1995 study conducted among inner-city black teens, James Johnson and colleagues reported that girls exposed to eight sexist, nonviolent rap videos were more accepting of teen dating violence than were girls without such exposure; boys' attitudes were not affected. Similarly, in their 2005 study L. Monique Ward and colleagues reported that middle-class black students exposed to four stereotypical music videos offered stronger endorsement of sexual stereotypes than did students exposed to neutral videos. Third, these links appear to affect viewers' actual preferences and behavior. In a 1978 study conducted by Shirley O'Bryant and Charles Corder-Bolz, exposure to images of women in nontraditional roles (e.g., pharmacist) increased young black girls' preferences for stereotypically masculine jobs. Looking at sexual behaviors, Gina Wingood and colleagues (2003) discovered that frequent viewing of music videos among black female adolescents was linked with a greater number of sexual partners and a greater likelihood of acquiring an STD one year later. Taken together, these findings suggest that, among black viewers, especially girls, frequent media exposure is associated with holding more stereotypical beliefs about the sexes and about sexual roles.

Although fewer in number, findings also extend to beliefs about violence and actual risk taking. In their 1993 survey of teen media habits and risk taking, Jonathan Klein and colleagues noted that, for black female teens, greater exposure to rap music predicted more risk taking. For black men, greater use of the

radio and of sports magazines predicted more risk taking, whereas greater exposure to TV news predicted less risk taking. In a 1995 experiment, James Johnson, Lee Jackson, and Leslie Gatto found that black adolescents exposed to violent rap music videos expressed greater acceptance of the use of violence and a greater likelihood of engaging in violence than did participants in the control condition.

Racial Attitudes

A final domain of normative beliefs likely to be shaped by media use are beliefs about race. In our highly segregated society, children's opportunities to interact with people of a different ethnic group are sometimes limited. For many, the most regular "contact" with children from other ethnic groups may come through the media. What does repeated exposure to media portrayals teach young black viewers about race in America? Surprisingly little published research has addressed this question, with most of the existing studies focusing on adults or on whites' beliefs about blacks. Testing the positive power of the media, Alexis Tan and Denise Kinner, in a 1982 experiment, examined whether exposing black 9-year-olds to media images of black and white children interacting well as friends would affect their desire for similar interactions. As expected, the black students who saw the 30-minute PBS film featuring such interactions expressed significantly more willingness to engage in friendly social interactions with white children than did participants in the control group. Showcasing the negative power of the media, James Johnson, Sophie Trawalter, and John Dovidio, in their 2000 experiment, found that listening to violent rap music influenced black and white college students' perceptions of other black people. Here, exposure to such music encouraged students' labeling of a hypothetical black target's behavior as being due to his "violent nature," but it had no such effect for the white target. Listening to violent rap music also affected their perceptions of the intelligence of the black target but not the white target. Finally, documenting the potential long-term effects of media exposure on blacks' racial attitudes, Paula Matabane (1988) found that higher levels of television viewing were related to greater belief in racial progress and integration. Surveying 161 black adults, she found that frequent television viewers were more inclined than infrequent viewers to believe that blacks fit in to society and are similar to whites and to overestimate the size of the black middle class. Although it is difficult to draw conclusions from these few published studies about the effects of entertainment media on the racial attitudes of African American youth, evidence emerging thus far suggests both a strong potential and a need for further research.

—L. Monique Ward and Khia A. Thomas

AGENDA CUTTING

Agenda cutting is the process by which deserving news topics are neglected. The phenomenon of agenda setting is well established and refers to processes by which topics get preferred attention in news provision. A natural corollary of this is that other topics will receive less attention than they may "deserve" (a topic or story can be said to deserve attention if it deeply affects the lives or interests of a substantial segment of the population or could do so). This process of agenda cutting differs from censorship, in which an administration or authority uses punitive sanctions to block coverage of matters that it desires or is required to keep from public knowledge or attention.

Agenda cutting can be found not only in print media but in the data elicited by Internet searches. For example, Bradley S. Greenberg of Michigan State University notes that a Google search on Sullivan's Island, South Carolina, provides evidence for and even quantification of the phenomenon. He found that a Google search using the keyword "Sullivan's Island" brought up about 100 websites describing Sullivan's Island's vacation amenities, history involving Edgar Allan Poe, and a stirring fight against the British in 1776. But one has to enter a further search descriptor, "slavery," before it then becomes clear that Sullivan's Island, near Charleston, was the first stop for many Africans who were brought to the New World as slaves. Between 1700 and 1775, 49% of all enslaved blacks came to America through South Carolina. This part of Sullivan's Island's past warrants attention and could make it an important tourist destination for those interested in the history of slavery.

An article by Roy Greenslade (2004) in the *Guardian* newspaper described an example of agenda cutting in the British press. The article noted that, for many years, newspapers treated the topic of child abuse as taboo, barely reporting on cases unless the assaults were carried out by strangers. Editors thought abuse within the family was too rare to warrant coverage and that intimate details of such crimes should remain private. The author argues that, even in the 21st century, coverage of child abuse is erratic and often inaccurate.

Another part of the reason the agenda is narrowed lies in our own preferences and behavior as viewers and readers. Teenagers more often watch music and entertainment on television, rather than news. Viewers who create the swelling market for systematically misnamed "reality programs" prefer to engage with

human relations trivia rather than with problems of profound substance and impact on society. They may correctly identify the reported romances of movie and music stars, while remaining (relatively) unaware of the composition of the U.S. Supreme Court or the location of Guantanamo and the controversies concerning suspected terrorists held there by the United States. Thus, viewer preferences can provide commercialized mass message systems with a rationale for agenda cutting and for a focus on entertainment instead of news and investigative reports.

AGENDA SETTING

At the very core of the still-emerging discipline of media studies lies the concept of agenda setting. Developed some 50 years after Walter Lippmann wrote of press-mediated "pictures in our heads" in his seminal *Public Opinion,* the agenda-setting concept identifies a high correlation between the priority that media-makers assign to specific issues and the importance that their audiences place on those same issues. According to agenda-setting theory, the media might not tell us what to think about such an issue as abortion rights, for example, but they do influence our becoming aware of the issue, assigning it a high degree of importance, and eventually forming an opinion on it.

THEORETICAL BACKGROUND

Within the tradition of media effects research, agenda setting is arguably a middle-of-the-road theory in terms of the kind of media influence it describes. It does not argue that audience attitudes and behaviors are largely unaffected by the media, as did the *limited effects theories* of the 1950s. Neither does it seek to minimize the existence of individual agency in the media consumption process (like the *magic bullet theory* of the 1940s and the more sophisticated *powerful effects theories* of the 1990s). The agenda-setting concept draws on an understanding of media-makers (particularly journalists) as *gatekeepers* of information, whose priorities and decisions shape (and limit) the issue coverage that is available to the public. The agenda-setting theory takes the gatekeeping concept one step further by formulating a connection between news items that are allowed through the gate onto TV screens and into newspapers and the issues audiences hold to be of importance to their own lives.

PAST AND FUTURE RESEARCH AVENUES

The first study that investigated that effect (and the first one to use the term *agenda setting*) was published in 1972 by Maxwell McCombs and Donald Shaw. One hundred undecided voters in North Carolina were surveyed with respect to the issues that most concerned them in an upcoming election. In addition, the authors undertook a content analysis of local media. The results pointed to a high correlation between the issues that had been heavily covered in the news and the issues that the surveyed subjects indicated as playing an important part in their voting decisions. Since 1972, more than 250 studies have addressed the agenda-setting function of the media in dozens of countries around the world. Most of these investigations, however, have followed McCombs and Shaw's precedent in focusing on the correlations between issue prioritizing by the media and issue prioritizing by adult audiences, in the context of public (often election-related) affairs. The agenda-setting paradigm still holds promise for researchers studying media effects on children and teenagers as well as on adult perceptions and attitudes outside the political realm.

AGGRESSION, ADVERTISING AND

Although the presence of aggression in television programming has been thoroughly investigated, aggression in television commercials has received considerably less attention from researchers. However, the study of aggression in television commercial content (especially commercials frequently viewed by children and adolescents) is indeed important, given that approximately 15% to 20% of all television content is devoted to commercials, with the average viewer exposed to approximately 60,000 commercials per year. The fact that children and young people are likely to be exposed to such a vast number of advertisements during their lifetimes makes the presence of aggression in television commercials a fertile area of research. This entry examines research on commercials during children's programming and during televised sporting events.

COMMERCIALS DURING CHILDREN'S PROGRAMMING

The few studies examining aggression in commercial content are typically confined to children's programming and sports programming. To date, only one published study, by Brendan Maguire and colleagues (2000), has examined aggression in commercials during general audience programming, finding 3% of the sample to feature aggressive portrayals. Interestingly, the studies investigating children's commercials indicate a higher percentage of violent portrayals than in commercials aired during other kinds of programming. In fact, in one of the most recent studies to examine this topic, Mary Larson found that of 37% of children's television commercials feature at least one act of physical, verbal, or object aggression.

While we know that aggression is somewhat prevalent in children's commercials, when and in what form is aggression most likely to appear? Research indicates that, when aggression is featured, it tends to be in commercials that target a young male demographic and feature male characters only. Aggression is found slightly less often when commercials feature both male and female characters. However, when commercials feature only female characters and are targeted to a female child audience, aggression is virtually nonexistent. Of all the commercials targeting children, aggression appears to be linked most to toy products, food products, and promos for upcoming television programs or movies.

The most recent research indicates that fortuitous aggression (i.e., accidental harm or acts of nature resulting in destruction) is the most frequent form of aggression shown in children's commercials, followed by object aggression (e.g., a character punching the wall) and physical aggression (e.g., a character punching or hitting another character), with verbal aggression (e.g., yelling, making sarcastic remarks, etc.) being least common. Larson concluded that these findings are of particular concern because of the fairly substantial presence of violence during children's television commercials, coupled with the fact that commercials featuring child characters offer young viewers many models of aggressive behavior.

COMMERCIALS DURING SPORTING EVENTS

Beyond the advertisements aired during children's television, researchers have also analyzed the content of commercials aired during televised sporting events, given that televised sports (considered "family-friendly programming") are often viewed by children. To assess the presence of aggression in sporting-event advertising, Charles Anderson (1997) studied commercials aired during the major league baseball playoffs of 1996, discovering that 7% featured at least one violent act and 6% had at least one violent threat. When Anderson (2000) repeated his study to examine the 1998 major league playoffs, he found that the rates of violent acts and threats had increased slightly. Most

recently, research on commercials aired during the highest-rated sporting programs suggests a lower level of aggression but a somewhat higher level of "unsafe behaviors" depicted in 14% of all commercials. Interestingly, commercials for television programs and movie promos accounted for 86% of all violent commercials aired during televised sporting events. Scholars also note that it is counterintuitive to find such commercials in family-oriented programming, and that it is challenging for parents to avoid exposing their children to aggression and unsafe behaviors.

CONCLUSION

Many important conclusions can be drawn from this body of literature. Indeed, the presence of violence and aggression in television commercials varies, ranging from 3% in general audience commercials to as much as 37% in children's commercials. However, it is noteworthy that the level of aggression found in children's commercials is significantly less than that found in children's programming, a genre in which 66% of all programs feature violence, according to the National Television Violence Study. Although this is an important comparison to note, children's exposure to aggressive commercials (much like their exposure to aggressive programming content) is cause for concern. Many consider children to be more vulnerable than adults to portrayals of television violence. In fact, research has suggested that children's exposure to violent images can lead to fear, aggression, and desensitization. Thus, commercials featuring aggression contribute to children's overall consumption of violent content, which can play a role in viewers' aggressive thoughts, attitudes, and behaviors. Furthermore, under the present ratings system, parents wanting to shield children from televised violence can make informed choices about television programming, but the same cannot be said for television commercials (as there is no ratings system in place to warn parents about the content of commercials). Ad-skipping technology, heightened parental supervision of television viewing by children, and more responsible content production by advertisers are among the efforts that could help to ensure that the viewing of programs and commercials is a safe experience for children.

AGGRESSION, ELECTRONIC GAMES AND

The emergence of new entertainment media has been followed time and again by concern about their potential harmful effects on children and other members of the public. This occurred with the advent of the penny press, dime novels, comic books, film, radio, and television. All have been denounced by social critics and

some scholars for the violent content they present and the antisocial consequences alleged to result from their use. In tandem with this, following every allegation, supporters of each new medium have dismissed critics and claimed that evidence failed to support claims of antisocial influence. These same concerns and allegations have been aimed at electronic games. Foremost among these concerns are questions about aggression in response to electronic game violence. Evidence suggests that playing violent electronic games can produce responses linked to aggressive behavior in children and adolescents; however, careful interpretation of this evidence is needed, and many questions remain unanswered. Still, given the wide exposure of children and adolescents to these games, an important challenge for parents is to monitor the content of the games played by their children and to teach the children to make sense of it.

In media effects research, definitions of aggression refer mainly to behaviors that are intended to cause harm to another person. Since the 1980s, research has focused on the violent content of electronic games and patterns of game use. Studies have also investigated the theoretical mechanisms linking electronic game violence to aggression, as well as the factors that might moderate this association. Much of this research has been based on theory associated with exposure to violent television. There is general agreement among researchers that exposure to television violence has a discernable influence on aggression. Some consider this influence to be small, whereas others regard it as more substantial. In either case, most experts agree that the unique attributes of electronic games make the experience and the effect of playing electronic games distinct from watching television.

THEORY AND RESEARCH

Literature developed across several disciplines explains the origins of human aggression and its association with media violence. Recent theory explains the enduring effects of media violence as originating in part from observational learning and desensitization, whereas short-term effects may be based on arousal and activation processes. An overview of factors that link aggression with media violence and electronic games in particular is provided by the general aggression model. This model describes how characteristics of a person and the environment interact to influence aggression, which is seen as an outcome governed largely by the learning and the activation of related knowledge structures, or thoughts that are brought to mind.

Short-term influence is said to result from personal variables (such as aggressive personality and situational variables (such as provocation or exposure to violent media) that activate thoughts related to aggression. The activated thoughts can bias automatic appraisal and response processes that govern both immediate and delayed aggressive behavior. For instance, a violent electronic game may promote aggression by increasing arousal or by priming hostile thoughts and affect. The account of long-term effects incorporates learning mechanisms to show how short-term experiences promote lasting change in the personal and situational variables that regulate aggression. Beginning at infancy, children learn how to interpret and respond to events through repeated rehearsal and reinforcement. Each short-term experience with violent media provides another learning trial that may influence the enduring composition of aggression-related knowledge structures and subsequent real-life aggression.

EMPIRICAL FINDINGS

Many studies provide empirical evidence related to issues of how state-of-the-art violent electronic games might influence aggression. Meta-analyses of empirical findings from more than 30 studies testing the relationship between video game violence and aggression show a significant average effect size for hostile cognitions, hostile affect, and aggressive behaviors. These effects remain the same for males and females, children and adults. In one meta-analytic review by John Sherry (2001) at Michigan State University, findings revealed a trend showing greater effect sizes for more recent studies—a fact consistent with claims that newer games are more potent along dimensions that influence aggression.

Violent electronic games may be particularly influential because of some unique attributes, including the games' ability to provide children with a first-person point of view, an active role in decisions to aggress, and a compelling reward structure. Some games provide a first-person point of view that may help a child identify with the aggressor, a factor known to increase short-term aggression following exposure to television. Over the long term, games give children an active role in decisions to aggress, something that may help develop more complete aggressive knowledge structures than passive television viewing. Added to

this, many games have a reward structure that may induce repeated decisions to aggress, something that should advance the learning and availability of these aggressive knowledge structures. Still, questions remain concerning the precise nature of these knowledge structures and the strength and influence that electronic games exert. Some researchers argue that electronic games should have a stronger influence on aggression than other media because of their interactive nature. However, Sherry points to meta-analysis on aggression showing that the effect size for playing violent electronic games is small compared to that for watching violent television. The factors controlling this are not completely clear.

MEDIATORS AND MODERATORS

We know from numerous studies of TV that not all violence is the same. The way violence is portrayed and the way viewers interpret it are important moderators of aggressive effects. Meta-analysis of research on TV violence and aggression reveals that the largest effects on aggression come from portrayals in which sympathetic, appealing characters commit violence that is rewarded, justified, and realistic. Violence by unappealing characters that is unrewarded and unjustified reduces the influence of the exposure. The same content features in electronic games should be expected to moderate the influence of violent games on aggression. However, beyond these game content features, attributes of the child are also expected to moderate the influence of game play. Differences in the child's developmental stage, personality traits, and interpretations of the game should moderate the influence of violent content on aggression.

Evidence suggests that personality factors play an important role in the selection of and reaction to electronic games, but the findings are varied and as yet provide no solid foundation for clear predictions about how personality moderates the association between aggression and electronic games. In a similar manner, media scholars have argued for decades that the manner in which individuals interpret media experience is a critical determinant of media content's influence, but there is little research yet examining individual interpretations of electronic game violence. Two areas that have received more attention are age and sex and their association with the outcome of game play. We know, for example, that males spend more time playing electronic games than females and that they prefer more violent games, but to date there is no evidence that violent games influence aggression more in males than in females. Similarly, we know that young children begin to spend more time playing games as they age and that their preference for violent games increases also. It should come as no surprise that children begin to prefer violent games as they mature. We know from research on television that, as children age, they become less frightened by fictional danger and violence such as that found in electronic games, but we do not know how this relates to the influence of violent games on aggression.

EXPOSURE TO VIOLENT CONTENT IN ELECTRONIC GAMES

The evolution of electronic games has been accompanied by considerable change in the amount of violence contained in games as well as the type of violence and the context within which it is portrayed. The crude forms of fighting and killing by cartoonlike characters or the unrealistic starship gunfights in early games are quite mild when compared to the levels and forms of sophisticated violence in newer games. Information about the presence of violence is included in assessments from the Entertainment Software Rating Board (ESRB), an industry source for ratings on the age-appropriateness of electronic games. ESRB rates games as *EC* (Early Childhood), *E* (Everyone), *E10+* (Everyone 10 and older), *T* (Teen), *M* (Mature), *AO* (Adults Only), and *RP* (Rating Pending), with distinctions for different levels of violence beginning at *E*. Academic study provides more detailed knowledge of this violence through content analysis.

Although estimates by academic researchers vary somewhat, studies of the most popular electronic games indicate that violence and physical aggression are contained in more than 70% of these games. Not surprisingly, the amount of violence varies by game genre and rating, with violence appearing in essentially all role-playing games and in more than 85% of all strategy and action games. In terms of game ratings, violence is present in most games aimed at young audiences (e.g., games rated *E*), but the actual amount of violence contained in electronic games is difficult to specify. Violence encountered during use varies according to how each person plays the game. However, research has estimated that games rated

E contained more than one violent interaction per minute on average, whereas games rated *T* and *M* contained more than four. In terms of violent context, research mirroring protocols from the *National Television Violence Study* has shown that patterns of aggression in electronic games primarily depict human characters using weapons to perpetrate violence that results in the bloodshed of victims. Further, violence is represented predominantly as justified, usually rewarded, and almost never punished. This violence can be quite graphic in *M*-rated games such as *Manhunt,* where vividly represented beatings and stabbings cause blood to spurt in all directions. Many *T*-rated games as well contain content fitting the ESRB descriptor categories of "blood and gore" and "intense violence."

The context and extreme levels of violence in games rated *M* would be inconsequential for children and adolescents if these games were played only by adults, but this is not the case. Research shows that games are played by more than 90% of American children and that violent games are among the most popular entertainment products for teens and adolescents, especially boys. Preteen and teenage boys report that they have no trouble buying games rated *M* and that their parents do not check the ratings of games that they play. Estimates of time spent playing electronic games vary by age, with children from ages 2 to 7 spending less than 5 hours a week and older children playing 7 hours or more. At more than four violent interactions per minute, those playing *T*- or *M*-rated games will be exposed to hundreds of violent interactions each week.

THE APPEAL OF VIOLENT ELECTRONIC GAMES

The attraction of adolescent males to violent content is well established in research on other media, and although research on electronic games is sparse, the same appears true here. A longitudinal study on third- and fourth-grade German children showed that violent games became more attractive for both boys and girls as they got older, although they were not a popular pastime overall at that age, particularly among girls. Research in the United States shows that, by the seventh and eighth grades, games with violent themes were played by more than half of all children observed. Survey research reports that adolescents play mostly for the sake of enjoyment, and although reports consistently show that gamers enjoy playing, little research shows exactly why.

We do know from research that aggressively disposed adolescents prefer electronic games with violent content and that they play for longer periods of time. A survey of American students in the eighth and ninth grades found that adolescents who were more likely to get into arguments with teachers and fights at school spent more time playing violent games. Similar patterns occur in the German sample of third- and fourth-grade children, which showed that children rated as more aggressive by their teachers and peers spent more time playing electronic games.

FUTURE RESEARCH

Despite the evidence that playing violent electronic games influences aggressive behavior in children and adolescents, the amount and diversity of research in this area justify a careful causal interpretation of the relation between violent electronic games and correlates of aggression, particularly in terms of short-term response. Questions remain about the magnitude and nature of this effect. Cautious reviewers rightfully point to the fact that the limited research in this area cannot answer important questions about the range of outcomes that are influenced by violent games or the magnitude of their influence. We do not know enough about the features of different game content or about characteristics of children that increase and decrease their vulnerability to game influence. Most notably, research using the type of controlled experiments and longitudinal designs needed to tell about long-term effects on children and adolescents is lacking. Yet, this is changing.

The National Science Foundation has begun to fund long-term studies on this topic at institutions such as Michigan State University and the University of Michigan. In addition, experimental research examining the neurobiology of aggression and violence offers promise. Research by René Weber (2006) at Michigan State University and his colleagues using modern brain imaging technology shows that electronic game violence evokes brain activity patterns similar to those found with actual aggressive behavior. Comparable research specifically on adolescents reports similar findings with exposure to violent television. Notably, research by Vincent Mathews at Indiana University and his colleagues indicates that this type of brain

activity following exposure to highly violent media is the same in normal adolescents as in those diagnosed with aggressive, disruptive behavior disorders.

RECOMMENDATIONS FOR PARENTS

Actions by policy makers can limit possible harm to children and adolescents by developing a universal rating system that eliminates confusion for parents and by passing legislation that restricts minors from gaining access to violent electronic games without parental permission. At the same time, the active involvement of parents in the selection and monitoring of games played by their children has the strongest potential for benefit. Experts in this area recommend that parents become wiser consumers who avoid the purchase of potentially harmful electronic games, restrict their children's access to violent games, and limit the time spent playing video games overall. Just as important is the need for parents to communicate with children and explain why violent games are harmful. Children should be made aware of the lessons that are taught by games where characters often try to harm each other, where harm is rewarded or portrayed as humorous, and where violence is always shown as the best way to overcome obstacles and solve problems. A child who becomes a wise consumer will make better decisions when parental guidance is absent.

AGGRESSION, MOVIES AND

With the advent of mass media, children's exposure to violent images has become a widespread public concern. This entry focuses on the effects of movies on aggression in children and youth, which have been examined through both quantitative and qualitative research. Quantitative research provides evidence of a correlation between movie violence and aggression, while qualitative researchers have attempted to understand the varied ways in which children and adolescents experience such violence. Both quantitative and qualitative researchers agree that aggressive behavior is not likely to result from a single cause. Parental influence, family environment, mental health, and the influence of peers are all important influences. Movie violence is thus one of many potential factors contributing to aggressive behavior in children and youth.

ISSUES IN RESEARCH ON MOVIE VIOLENCE

From the 1920s to the present, hundreds of studies have been conducted to determine whether movie violence causes aggression in viewers. However, it must be noted that many studies conflate movie and television effects, with the findings generalized to both forms of media. Although there are many similarities between the two, there are also some differences. Violence in movies is often presented more realistically, more graphically, and in larger-than-life images, thus heightening the intensity of the viewing experience. In addition, viewers watch movies more attentively in comparison to television, which is watched in the home environment and therefore one may be distracted and watch with less involvement. However, due to the accessibility of television, viewers are exposed to more violence in TV programs than on film. Further complicating the issue is the fact that movies can also be watched at home on the TV screen. However, despite some differences, concerns about the violent content of movies and TV are generally the

same. One of the persistent questions has been whether exposure to these violent images causes aggression in children and youth.

At least two primary areas of contention exist among researchers who investigate this topic. The first is the problem of defining and operationalizing the terms *violence* and *aggression. Violence* is generally defined as an extreme form of aggression involving intention and harm and resulting in acts such as aggravated assault or murder. However, it can be depicted in animated films, dramas, comedies, horror movies, action movies, science fiction, war stories, and documentaries. Because violence can be presented in widely varying forms, generalization about effects becomes problematic. Studies have demonstrated that violence portrayed humorously, for instance, may be interpreted differently from violence presented realistically. Other contextual factors have also been shown to affect interpretation and impact, including identification with the perpetrator or victim, motives for violence, consequences of violence, and the nature, duration, and graphic nature of the violence.

Aggression is typically defined as behavior directed toward another with the intent to harm. Studies of aggression often include verbal as well as physical acts. A key area of disagreement among media researchers is whether aggressive play, often known as rough-and-tumble play, should be grouped together with other forms of aggressive behaviors (pushing, hitting, shoving). Many researchers have included rough play in their measurements of overall aggression in children. However, this has been disputed, as there is no intent to harm. Such play demonstrates excitement and arousal but not necessarily aggression.

The second major area of contention in the research on movie violence pertains to the methods of investigation. The literature on media effects has emerged from two divergent traditions of inquiry. The first tradition is that of quantitative research based on experimentation, statistical analysis, and generalization from one sample population to another. Qualitative research represents the interpretive tradition of inquiry, focusing on smaller populations and emphasizing in-depth observation and interviews in natural settings, thick description, and a belief in the social construction of meaning. Researchers in these two traditions ask and answer different types of questions and explicate different aspects of the area of investigation.

QUANTITATIVE RESEARCH

The vast body of research on media effects has been produced by randomized experiments most often conducted in a laboratory setting and less frequently in a field setting. Statistical proof for effects is sought by isolating key factors and controlling for the influence of others. Early laboratory research focused on direct cause and effect; however, more recent studies have attempted to identify intervening variables that might impact the effect being studied. The most common research design has been to randomly assign participants to view either a violent or a nonviolent film clip and then to place them in a situation where they have the opportunity to demonstrate aggression. Children are typically placed in a play setting and observed for aggressive behaviors. In field studies, they are shown movies in their classrooms or residences, with observation of their behaviors following the viewing. Findings indicate that viewers who watched the violent movie clips tended to exhibit higher levels of short-term aggression. Meta-analyses have found larger effects in laboratory experiments than in field studies. There is also evidence that effects are stronger in children predisposed to aggressive behavior.

Although results have not always been consistent, the number of studies with significant positive findings indicates a causal link between movie violence and short-term aggressive behavior for some children. Suggested explanatory factors include increased physiological arousal and excitation, the triggering of preexisting aggressive thoughts, and the tendency to identify with aggressive characters and imitate their behaviors.

Critiques of these studies pertain to the definitions of aggression and the constraints of the laboratory environment. As noted above, playful aggression is not often distinguished from behavior with intent to harm. Also, the proxies for aggression used in the laboratory settings (popping balloons, giving noise blasts, punching Bobo dolls—inflatable, egg-shaped balloon creatures with weights in the bottom that makes them bob back up when knocked down) are different from real acts of aggression. These experiments do not inform us about long-term effects or tell us whether the same effects would occur in a real-world setting. Lastly, experimenter demand may come into play when subjects behave in certain ways due to their perceptions of researcher expectations.

Surveys have also contributed to the literature on viewing habits and aggressive behavior. TV and

movie viewing are often considered together in assessing the amount and content of media violence viewed. This information has usually been gathered through child self-reports or provided by parents. Correlations between the amount of media violence viewed and levels of aggressive behavior are in the small-to-moderate range and are higher for younger children than for teenagers. However, establishing an association between the two factors does not demonstrate that media violence causes the aggressive behavior. For example, children predisposed to aggression may be more likely to watch movies containing violence. Other factors may also be involved; for instance, alienation from peers has been shown to be predictive of violent film viewing and could also be related to aggressive behavior. The longitudinal research investigating viewing habits and aggression has primarily focused on television and is not discussed here, except to note that, according to the surgeon general's 2001 report on youth violence, the best predictor of future aggressive or violent behavior is past history of aggression and violence.

In summary, survey research provides evidence of a correlation between media violence and aggression. Randomized laboratory and field studies indicate that the former may cause short-term aggressive behavior in some individuals. However, researchers agree that the effects account for only a small part of the variance in aggressive behavior. Human aggression is a complex and multifaceted phenomenon, and media messages do not operate in a sociocultural vacuum. Each of us brings a unique set of beliefs, values, traits, and social, cultural, and personal history to the viewing experience. The combination of these individual characteristics affects what we view and how we make sense of it. It is in this area that qualitative researchers contribute to our understanding of movie effects.

QUALITATIVE RESEARCH

Qualitative researchers assert that violent media mean different things to different people. They have attempted to understand how children and youth think, talk about, and interpret violence in movies and television. Uses and gratifications research has focused on the way that individuals actively use the media for different purposes and pleasures. The violence contained in heroic tales or animated films, for instance, may fulfill a need in children for power and agency. Violent movies can also provide thrills and serve a social purpose in talking about the movie with peers. Research from cultural studies has further demonstrated that young viewers decode and interpret the dominant messages of the media in different ways, including acceptance, negotiation, and resistance. Thus, not all children will interpret movie violence in the same way nor be affected equally by it. Critiques of this body of research pertain to its interpretive nature, small study samples, lack of generalizability, influence of researcher expectations, and acceptance of children's responses at face value.

AGGRESSION, MUSIC AND

The content and messages of music lyrics is a controversy that started to gain public exposure and discussion around the 1960s, when music began to contain such themes as drug use, risky sexual behavior, and violence. In the early 1990s, this controversy surged again with the popularity of violent gangsta rap. Since then, there has been debate as to whether exposure to violent music lyrics can have a negative impact on youth.

It is no surprise that music plays a large role in the lives of American youth. Children and adolescents

spend hours listening to their favorite musical artists. Musicians are often idolized by youth, as evidenced by youth imitation of fashion styles, behaviors, and product selections. A 2004 study by Gentile, Lynch, Linder, and Walsh estimated that children spend 21 hours per week listening to music—comparable to the amount of time youth spend watching television. Moreover, this may be an underestimate because music is often played in the background while other activities are taking place (e.g., doing homework, talking with friends, playing video games). Inventions such as the iPod and MP3 stick make it possible for people to listen to music almost anywhere.

EXPERIMENTAL RESEARCH ON VIOLENT MUSIC LYRICS

The current research literature on the effect of violent music lyrics is rather small compared to the research on violent television or even violent video games. In addition, the findings from the few studies that have been conducted are mixed. There is some evidence that exposure to violent music can increase aggressive cognitions, affect, and various attitudes concerning violence. One possible reason for such inconsistencies in the current literature is methodological problems in the current research.

Controlling for Music Tempo Differences

Music can be divided into two primary parts: music (tempo, volume, intensity, etc.) and lyrics. Each of these components of music has been analyzed separately and together. In 1984, McFarland examined whether exposure to different tempos of nonlyrical music (tension-inducing music, relaxing music, or no music) had an effect on undergraduate listeners completing the Thematic Apperception Test (TAT). In the TAT, participants view ambiguous photos and then write a story that describes what is occurring in the photo. The TAT is used to measure emotions and personality characteristics. Participants who heard high-tension music wrote the most unpleasant stories, which could indicate more negative affect.

Although this study does not address the impact of lyrics on listeners, it does demonstrate that the tempo of music can have an impact on the listener. This finding is especially important to other music research, stressing that the type and tempo of the music must be controlled to examine the impact of lyrics on the listener.

Incomprehensible Lyrics

Another issue plaguing the current literature on music violence involves the ability of participants to comprehend the lyrics in the music stimuli. In rock and rap songs, it is often difficult for the listener to decipher what the singer is actually saying. For example, a study conducted by Wanamaker and Reznikoff (1989) exposed three groups of undergraduate participants to one of three conditions: (a) a song with violent music and violent lyrics, (b) a song with violent music and nonviolent lyrics, or (c) a song with nonviolent music and nonviolent lyrics. The results found no effect of violent music lyrics on hostility. However, only 23% of the subjects exposed to the violent song with violent lyrics correctly identified the main theme of the song.

Controlling Characteristics of Stimuli

Many media violence studies utilize only one stimulus per condition, and often those stimuli are not equated on various other characteristics (e.g., how exciting the stimulus is, etc.). For example, many studies have subjects listen to one specific violent song or one specific nonviolent song. Often, these songs are not equated on other characteristics. This omission can compromise the generalizability of the findings. If significant results were found, one must question whether these results are characteristics of all violent and nonviolent music or whether this finding was specific to the two music stimuli that were selected. Wells and Windschitl (1999) suggest sampling a range of stimuli from the population and using multiple stimuli to represent each condition. Also, stimuli should be controlled on various other characteristics so the researchers can be certain that the main manipulation is the amount of violence in the media.

Effect of Violent Lyrics on Aggression-Related Variables

Currently, only a small number of studies have investigated the relationship between exposure to violent lyrics and aggression-related variables.

In 2003, Anderson, Carnagey and Eubanks published five studies that experimentally examined whether exposure to violent lyrics compared to nonviolent lyrics can increase aggressive cognitions and aggressive affect. In all five studies, undergraduate participants listened to either a nonviolent or a violent song and then completed aggressive cognition and

affective measures. All five studies found the same results: Exposure to violent music lyrics increases aggressive cognitions and aggressive affect.

For example, in the third study, the researchers exposed participants to (a) one of four violent songs, (b) one of four nonviolent songs, or (c) no song. Afterwards, participants completed a measure of state hostility and aggressive cognition, in a counterbalanced order. Next, participants rated their perceived arousal by the song and how well they could comprehend the lyrics. Results showed no difference in arousal or lyric comprehension between the violent and nonviolent song conditions. Results did show that subjects exposed to a violent song had more aggressive cognition than those not exposed to a violent song. Also, among participants who completed the questionnaire immediately after hearing the song, those exposed to a violent song were more hostile than those exposed to a nonviolent song. Because the violent and nonviolent songs were equal on lyric comprehension and perceived arousal, it is more likely that the differences found on the hostility and aggressive cognition were due to the amount of violence in the song lyrics.

Other studies have found that violent lyrics had no impact on aggression-related variables. For example, Ballard and Coates (1995) conducted a study in which undergraduate participants heard one of six songs varying in genre (rap vs. heavy metal) and lyric (homicidal, suicidal, neutral). After listening to the randomly assigned song, participants completed various scales that included measures of suicidal thoughts, depression, state hostility, and self-esteem. Results showed no difference in state anger between the lyric content conditions. Participants, however, completed the state anger scale after completing numerous other scales. This delay in time and interference from other scales could account for part of this null finding.

A study conducted by Wester, Crown, Quatman, and Heesacker (1997) examined whether exposing male undergraduates to violent lyrics affected attitudes towards women. Participants were exposed to (a) sexually violent music with violent lyrics, (b) sexually violent music without lyrics, (c) sexually violent lyrics without music, or (d) no music or lyrics. Participants then completed various attitude scales. Results found no difference in negative attitudes toward women among any of the four groups. However, participants who were previously exposed to violent lyrics (regardless of whether music was present or not) rated their relationships with women as more adversarial.

In a study conducted by Barongan and Hall (1995), results suggested that antisocial lyrics affect behavior; however, it is unclear that the examined behavior was actually aggressive. In this study, undergraduate males first listened to misogynous or neutral rap music. Next, participants viewed three vignettes (neutral, sexual-violent, assaultive) and then selected one to be shown to a female confederate. Participants who were previously exposed to misogynous lyrics significantly more often selected the assaultive vignette to be shown to the confederate female. Currently, there is no research that clearly examines the causal effect of violent music lyrics on aggressive behavior.

CORRELATIONS BETWEEN MUSIC PREFERENCE AND MALADAPTIVE BEHAVIORS

There is some evidence that music preferences are related to certain maladaptive behaviors. In 1994, Took and Weiss demonstrated that adolescents' preferences for rap and heavy metal music were correlated with numerous maladaptive behaviors related to both academic performance and other behaviors outside of the classroom. Rap and heavy metal music was negatively correlated with academic performance and positively related to school behavioral problems. Self-reported drug use, arrests, and sexual activity were also positively correlated with rap and heavy metal music preference.

A more recent study by Rubin, West, and Mitchell (2001) demonstrated that music preference was correlated with various negative attitudes. Undergraduate students whose favorite music was rap or heavy metal had more hostile attitudes than students who preferred other music types (e.g., adult contemporary, dance, country). Students who preferred heavy metal music displayed more negative attitudes towards women than other students who preferred different music genres. Rap music fans displayed higher distrust of others compared to other music genre fans.

In conclusion, music with violent lyrics appears to increase aggression-related thoughts and feelings, but the link between violent lyrics and aggressive behavior is less clear.

AGGRESSION, MUSIC VIDEOS AND

Almost from the day of the launch of MTV (Music Television) on August 1, 1981, music videos have been accused of being excessively violent and of contributing to the culture of violence in the United States and around the world. Such allegations of social and psychological harm from watching violence in music videos are often based on fallacious assumptions or other informal or scientific fallacies, but some evidence of antisocial behaviors resulting from watching violence-laden music videos does exist.

VIOLENT CONTENT

Music television has evolved into several channels, the most popular of which are MTV, VH-1 (Video Hits 1), BET (Black Entertainment Television), and CMT (Country Music Television). Researchers have conducted several systematic content analyses to determine the level of violence portrayed on these music television networks. A 1997 study reported that between 11.5% and 22.4% of the videos shown on these music networks contained violent acts, and that 63% of the videos that were violent showed young people engaging in interpersonal violence. That same year, the American Academy of Pediatrics commissioned research evaluating 518 music videos. Approximately 15% of the videos contained interpersonal violence, with six violent acts on average per violent video. A 2002 study found that BET and MTV were more likely to feature violent videos than other music television networks, and 15% of all music videos contain at least one act of aggression. Summarizing across findings, it seems that roughly one out of every seven music videos aired on the major music television networks contains violent content.

A particularly detailed 1998 content analysis assessed characteristics of the perpetrators and victims of violence in music videos on the four major music television networks. In 391 videos in which gender of the aggressor and the victim could be determined, males were depicted as aggressors in 78.1% of the videos, and females perpetrated violence in 19.9% of the videos. The researchers indicated that gender of victims often was not as clearly identified as that of aggressors, but when coding of gender was possible, females were the victims 78.3% of the time. This finding suggests that, at best, music videos are perpetuating societal stereotypes; at worst, they are exacerbating them.

EXPOSURE

One of the periodic "criticisms" of music videos is that they are the provenance of young people, who are avid consumers of them. In other words, they are criticized because they are effectively marketed. Indeed, they are. A large-scale Annenberg Public Policy Center survey conducted in 1997 found that

53% of 10-to-17-year-olds watch MTV regularly. Another study found that 80% of 9th to 12th graders watch the channel, with an average viewing time of 2 hours per day. A third study reported that 73% of boys and 78% of girls between 12 and 19 years of age watch MTV, with an average of 6.4 hours per week viewing. Although the normative exposure data provided by these investigations differ rather substantially, it is obvious from all three sources that children and adolescents spend a great deal of time watching music videos. The argument is often made that such viewing displaces other, more productive activities. The argument that such regular and prolonged exposure to violence has antisocial effects is also common.

PUBLIC OPINION

Indeed, public opinion surveys reveal that caregivers and the general public believe that violence in music videos has deleterious personal and societal effects on consumers and should be more tightly restricted. A 2001 Gallup poll found that 38% of mothers surveyed thought that violence in music and other entertainment was an extremely important cause of school violence. Dovetailing with these findings, an earlier CNN/*USA Today*/Gallup poll found that 48% of Americans surveyed indicated that violence in popular music videos should be more tightly restricted and regulated. Moreover, politicians and other public figures frequently have claimed that viewing violent music videos leads adolescents to become antisocial, to engage in substance abuse, and to engage in Satanism, murder, suicide, sexual violence, and other acts of aggression.

EVIDENCE OF EFFECTS

Given the prevalence of violent content in music videos, their heavy consumption by allegedly vulnerable children and adolescents, and widespread public opinion that viewing violent music videos causes harm, it should be no surprise that the social scientific community has investigated the social and psychological impact of viewing violent music videos. Three late-20th-century investigations found that aggressive behaviors among adolescents decreased when music television networks were removed from the television viewing diets. Another study found that increased viewing of violent music videos was positively associated with increased acceptance of teen dating violence. A widely cited 2003 study reported a positive correlation between viewing MTV and physical fights among third- and fifth-grade children. More specifically, children who viewed high levels of MTV were rated by their peers as more hostile and relationally physically aggressive—and the children's teacher rated the heavy MTV viewers as more relationally aggressive, physically aggressive, and less helpful—than their peers who viewed less MTV.

A PERCEIVED DEADLY COMBINATION

Social critics have regularly lambasted the harmful social consequences of consuming rock music, which they have perceived to powerfully engage the emotions of vulnerable youth. Others have decried the antisocial potency of television. As might be imagined, the combination of these two allegedly powerful antisocial forces has often been perceived to be particularly deadly. Extant empirical evidence does not effectively refute such claims, although the robustness of the antisocial effects found has not been particularly high.

Undoubtedly, in fact, the etiology of violence is complex and multifactorial. Public concern about violence in music videos is often discussed against a backdrop of perceptions of increased interpersonal violence and increased violent crimes. In reality, when weighed against the prevailing normative data, such perceptions of escalating societal violence are erroneous. According to the U.S. Department of Justice, violent crime in the United States peaked in the mid-1990s and has been steadily decreasing ever since. But in the public psyche, perceptions are more real than evidence. And the heavy exposure by children and adolescents to music videos with violent content undoubtedly will keep the issue of the effects of violent music videos in the public mind long after empirical evidence has clarified the issue to the satisfaction of the scientific community.

AGGRESSION, TELEVISION AND

Since its introduction to American society at the 1939 World's Fair, television has become an integral part of nearly every home. Since 1985, about 98% of all households in the United States have owned at least one television set. It is estimated that there are more television sets in the United States today than there are toilets. TV ownership is also very high in most other industrial countries and even in many third world countries. There are not only more TV sets today than ever before, they are also on longer—more than 7 hours per day in most American homes. A large share of television programming contains violence, and researchers have found that TV violence increases aggression in both the short run and the long run. The effect is found among both children and adults.

CONTENT ANALYSIS OF TV PROGRAMS

Part of the National Television Violence Study in 1996, 1997, and 1998 included a comprehensive content analysis of more than 8,000 hours of television programming. Violence on television was defined as "any overt depiction of a credible threat of physical force or the actual use of such force intended to physically harm an animate being or group of beings." The analysis revealed that about 60% of programs contained violence. Fewer than 4% of the violent programs contained an antiviolence theme. Violence portrayed on television is often glamorized, sanitized, or trivialized. Nearly 40% of the perpetrators of violence were "good" characters. Even when the perpetrators of violence were "bad" characters, more than 40% went unpunished. Almost 75% of the perpetrators of violence showed no remorse for their actions. More than half the victims of violence showed no pain or suffering. Only 15% of the violent programs portrayed the long-term consequences of the violence for the victim's family, friends, and community. Even though more than half the violent scenes on television were lethal, more than 40% of them were portrayed as humorous.

EFFECTS OF TELEVISED VIOLENCE ON AGGRESSION

For more than 50 years, social scientists have investigated the effects of televised violence on aggression and violence. *Aggression* is typically defined as any behavior intended to harm another person. *Violence* is typically defined as a severe act of physical aggression, such as an assault. Thus, all violent acts are aggressive acts, but not all aggressive acts are violent.

Short-Term Effects

Experiments provide the best test of the short-term effects of TV violence on human aggression. Some experiments are conducted in a laboratory, and some experiments are conducted in a more natural setting (called a *field experiment*). In a typical laboratory experiment, participants are randomly assigned (by the flip of a coin) to watch a violent or a nonviolent TV show. Because participants are randomly assigned to groups, the same number of aggressive people who watch violent shows should watch nonviolent shows. The researcher treats the two groups the same, except for the show they watch. After the participants watch the show, the researcher measures how aggressively they behave. In laboratory experiments involving children, the aggressive behaviors tend to be somewhat mild (e.g., pushing and shoving another child). In field experiments with children, the aggressive behaviors tend to be stronger (e.g., fighting in hockey games). In laboratory experiments involving adults, participants often punish another person (actually an accomplice of the researcher) using electric shocks or loud blasts of noise delivered through headphones.

The consistent finding is that participants who watch violent TV shows behave more aggressively immediately afterward than do those who watch nonviolent TV shows. The effect of TV violence on aggression occurs regardless of gender, race, income, intelligence, or chronic aggressive tendency. Because these are experimental studies, we can conclude that exposing viewers to TV violence *causes* them to behave more aggressively in the short run.

Long-Term Effects

Longitudinal field studies provide the best test of the long-term effects of TV violence. A major issue in this type of research is whether watching violent TV

increases aggression or whether aggressive children choose to watch more violent TV. However, the research indicates that the violent TV increases aggression. For example, in a longitudinal study by Eron, Huesmann, Lefkowitz, and Walder (1972), the correlation between boys' exposure to TV violence at age 8 and their aggression at age 18 was .31, whereas the correlation of age 8 aggression with age 18 exposure to TV violence was about zero. In a 15-year longitudinal study conducted by Huesmann, Moise-Titus, Podolski, and Eron (2003), the correlation between a child's exposure to TV violence at age 8 and aggression 15 years later was significant for both men and women, even after controlling for level of aggression at age 8. High television violence viewers at age 8 were much more likely to have abused their spouses and perpetrated acts of serious physical aggression than were low television violence viewers. Similar effects have been found in longitudinal studies conducted in other countries, such as Finland, Poland, and Israel.

In summary, longitudinal field studies have shown that children who grow up watching a lot of TV violence are likely to behave more aggressively later in childhood, in adolescence, and in young adulthood. This finding holds up even if one controls for differences in initial aggressiveness, intellectual functioning, and social class. The bottom line is that, on average, TV violence is making our children behave more aggressively in childhood, and the aggressive habits they learn from TV in childhood carry over into adolescence and even young adulthood.

EFFECT SIZE

The entertainment industry claims that the effect of TV violence on aggression is so small that the risks to society and its members are negligible. However, Bushman and Anderson (2001) found that the effect of TV violence on aggression is larger than many other effects that people accept as indisputable facts, such as the effect of asbestos on cancer, the effect of lead poisoning on mental functioning, or the effect of secondhand smoke on lung cancer. A study by Bushman and Cooper (1990) found that the effect of TV violence on aggression is about the same size as the effect of alcohol on aggression. Thus, the size of the effect is substantial rather than trivial.

ALCOHOL ADVERTISING, EFFECTS OF

Research has established that children and adolescents see a great deal of alcohol advertising and that more

frequent exposure is associated with alcohol use. It has been more difficult, however, to determine whether more frequent exposure *causes* alcohol use. Recent studies increasingly make it appear that a causal link exists. Perhaps more importantly, scholars have begun to identify the conditions under which exposure to alcohol advertising predicts alcohol-related attitudes and behaviors. Generally, scholars believe that repeated exposure to alcohol advertising influences children to the extent to which their interpretations of messages lead them to conclude that alcohol use is normative, appealing, and rewarding. Effects are magnified if messages are reinforced by real-life observations.

Studies have verified that children's exposure to alcohol advertising begins early and greatly increases as they reach adolescence. Three of every four beverage ads in magazines and video programming popular among adolescents promotes an alcoholic beverage. Research indicates that alcoholic beverage advertisers spent more than $30 million to place more than 2,600 ads for alcoholic beverage advertising on the 15 television programs most popular with teens in 2003. The number of ads appearing in programs for which 12–to-20-year-olds composed more than 30% of the audience increased by 48.3% between 2001 and 2003. As a result, the average young person saw two beer ads for every three viewed by an adult in 2003, and three ads for fruit-flavored distilled spirits—commonly called *alcopops*—for every four ads seen by an adult.

Experiments and surveys with children and adolescents have found that those attracted to beer advertising are more likely to desire merchandise featuring beer themes and alcohol brand logos. The appeal of the merchandise is associated with earlier and more frequent use of alcoholic beverages.

It seems likely that young people would be influenced by such a torrent of messages. It is well established that commercial advertisers can influence children with strategies that show how products can meet their emotional needs and desires. For example, marketers recommend using young girls' desire for beauty, glamour, and fun to target them, and they recommend advertising that depicts power, bravery, or gross humor to target boys.

Marketers frequently employ these themes in alcohol advertising. It is unsurprising, then, that alcohol ads are well received by adolescents. Research indicates, for example, that 16- and 17-year-old adolescents, and especially boys who drink, like alcohol advertising featuring humor and sex, can correctly identify alcoholic beverage brands, and can recall the advertising specifically associated with each brand.

Meanwhile, many studies have indicated that, as young people's exposure to alcohol advertising increases, the likelihood of their experimentation with alcohol increases as well. The association between exposure and behavior, however, does not prove on its own that alcohol advertising influences children to become underage drinkers. Moreover, not all studies have found this association. Scholars therefore have turned their attention to the conditions under which children and adolescents internalize problematic messages about alcohol use. Studies have established, for example, that children develop expectations and intentions about alcohol use well before they begin drinking it.

Research indicates that preadolescent children are uniquely susceptible to the influence of advertising messages because they lack the cognitive skills of older children and are skillfully targeted by advertisers. Because children are still developing their critical thinking skills at least until the eighth grade, they tend to respond easily to characters that are strong, fun, popular, and attractive. Studies show that the techniques marketers recommend for use with children—and to which scholars show that children are susceptible—frequently are present in alcoholic beverage advertising. Indeed, many studies have verified that alcohol ads that include these elements appeal to children and adolescents. Some studies, including one

that asked underage drinkers if they thought they were targets of the ads, have concluded that advertisers intentionally target underage viewers.

Whether or not children constitute an intended target for alcohol advertising, research has shown that many preadolescents have favorite brands and a high affinity for alcohol ads and campaigns. They typically give alcoholic beverage advertising high marks for good music, bright colors, and a good amount of action, style, and humor. Positive responses to televised beer advertisements from 10-to-17-year-olds have been associated with an increase in the frequency of participants' current and future expected future drinking.

Some studies have used play behavior to study children's modeling of alcohol use while too young to obtain access to it on their own. These studies have found that children as young as 2 years of age drink alcohol and imitate purchasing and drinking behavior. They also have found that most children understand the difference between alcoholic and non-alcoholic beverages, along with social norms for the use of alcohol, by the time they enter elementary school. Elementary school children who find alcohol advertising appealing have been found more likely to choose an alcohol-themed toy, and the desire for such products have been found to associate with earlier use of alcohol among adolescents.

Ultimately, existing research indicates that children do internalize messages from alcoholic beverage advertising in their decision making about alcohol. Studies show that children are very much aware of alcoholic beverage advertising and that such advertising may have a stronger influence on young people than on adults. Some research suggests that an affinity for alcoholic beverage advertising associates with the age of reported first use and with heavier drinking among college students. Nevertheless, conclusions tend to be based on a variety of separate studies based on content analysis, exposure patterns, or receivers' interpretations of content. Studies often rely on cross-sectional survey designs or laboratory experiments. The need continues to exist for longitudinal field studies that bridge these methods to account for what appears to be children's gradual internalization of messages about alcohol into their decision making.

ALCOHOL ADVERTISING, INTERNATIONAL

All over the world, public health organizations promote restrictions on alcohol advertising because of the potential negative health consequences of alcohol

consumption. Health organizations are especially worried about the effects of advertising on minors, and, according to them, much advertising is especially directed toward young people because the alcohol industry needs to recruit new drinkers. This accusation is denied by representatives of the alcohol industry, who claim that advertising is not aimed at young people but that its purpose is to increase the market share of specific brands among existing users of alcoholic beverages. As a result of this debate, many countries have imposed restrictions upon the advertising of alcoholic beverages. Often, special restrictions are implemented with respect to advertising that targets children and adolescents.

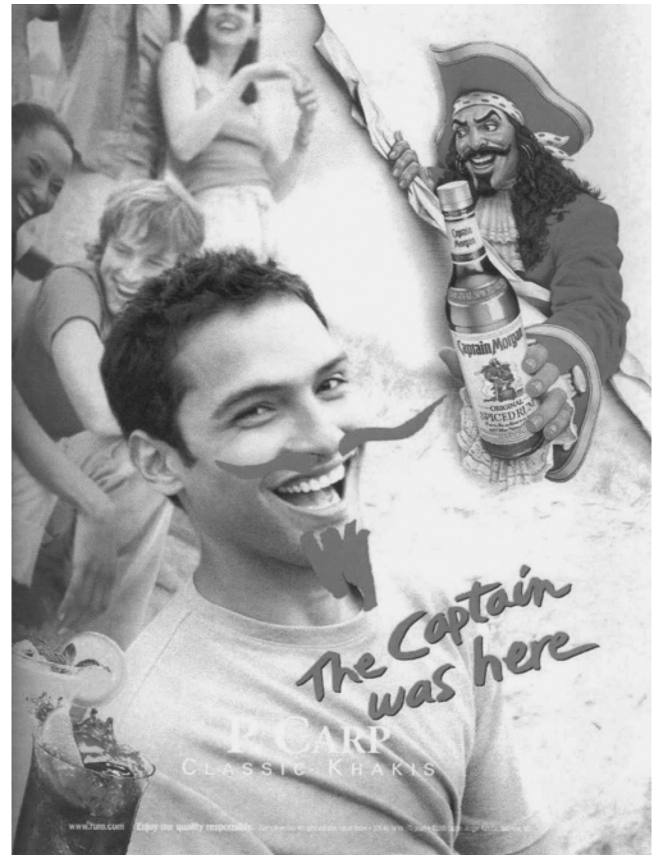
REGULATION OF ALCOHOL ADVERTISING

Two types of regulations restrict alcohol advertising: statutory regulations and nonstatutory self-regulations. Statutory regulations are embedded in law and issued by the government. Nonstatutory self-regulations are voluntary codes of advertising practices. These self-regulations are often issued by national nongovernmental organizations that are sponsored by the alcohol-producing industry. For instance, in the United States, the Beer Institute, which represents the interests of more 200 brewers, has developed an advertising code for beer advertising.

Both statutory regulations and nonstatutory self-regulations may contain restrictions on the media in which advertising is allowed as well as on the content of alcohol advertising. Also, the regulations may differ according to the type of alcohol. A report of the World Health Organization published in 2004 showed that alcohol advertising is banned completely in 5% of the countries (e.g., Norway). No legal or self-regulatory restrictions are imposed in 27% of the countries (e.g., Cambodia). Nonstatutory self-regulations are found in 10% of the countries (e.g., Australia), statutory regulations are found in 48% of the countries (e.g., Mexico), and a combination of voluntary and statutory regulations is found in 10% of the countries (e.g., Italy).

Advertising Bans

The most effective way to prevent alcohol advertising from reaching children is a complete ban on all advertising, but such bans are found in only 5% of the countries. More often, advertising is legally banned from a limited number of media. Advertising for alcoholic beverages that contain a high percentage of alcohol (e.g., spirits) are more often banned than advertising for alcoholic beverages that are low in alcohol (e.g., beer). For instance, 16% of the countries ban all beer advertising on television (e.g., France) but 29% ban television advertising for spirits (e.g., the Russian Federation). About the same proportion of restrictions is found with respect to radio advertising, but advertising in print media such as magazines is less often legally banned. Only 11% of the countries do not allow print advertising



Print and Web-based advertising for alcoholic beverages often features themes and images known to appeal to children and adolescents. These range from cartoons and animals to sexual stereotypes and slapstick humor. According to the Captain Morgan website, its top markets in 2005 included the United States, Canada, Great Britain, and South Africa. The company also states that Captain Morgan is the seventh-ranked "spirit" brand worldwide.

of spirits, and only 4% do not allow print advertising of beer.

Many regulations contain special provisions to prevent alcohol advertising from targeting minors. Regulations may ban advertising on billboards in school buildings or in the vicinity of schools (e.g., Denmark). Often, it is forbidden to advertise in print media the readership of which consists of a significant number of children and adolescents. The definition of *significant number* differs from country to country, but most often it is defined as 50% (e.g., United States) or 25% (e.g., The Netherlands). Similarly, advertising around television and radio programs that are watched or listened to by a majority of underage persons can be disallowed. Another approach to limiting children's exposure to alcohol advertising on television is to restrict the hours at which such advertising can appear. Regulations occasionally include rules that alcohol advertising on television cannot be broadcast before a certain time, which varies from 8 p.m. to 10:30 p.m. (e.g., Spain and Thailand). Advertising may also be prohibited at sporting, musical, or other special events that a significant number of children and adolescents attend as actors or spectators.

Restrictions on the Content of Advertising

Not only can advertising be banned, its content can also be restricted. Many countries have developed rules to prevent children and adolescents from being attracted to alcohol consumption as a result of advertising exposure. Examples are rules that ban the following content:

- Styles (e.g., cartoon characters, motifs, or colors) that appeal to young people or that are associated with youth culture.
- Prominent public figures or role models who appeal to minors (e.g., actors, sporting heroes, or pop stars).
- Depictions of children, adolescents, young-looking models, or (in particular) minors consuming alcoholic beverages. *Young-looking* usually is defined as under 18 or under 25 years of age.
- Portrayals of alcohol consumption that imply the achievement of social, sexual, or sporting success.
- Portrayals of alcohol drinking as a sign of maturity.

THE INTERNATIONALIZATION OF COMMUNICATION

Increasingly, a problem with national regulations is that advertising crosses borders. Magazines that are produced in countries that allow alcohol advertising may be for sale in countries that prohibit alcohol print advertising. Advertising around international sporting events is broadcast on networks all over the world, and music satellite channels can be received in numerous countries. In the last few years, the steep rise of Internet use has offered enormous new possibilities for advertising. These possibilities are used also by the alcohol industry, and practically all brands have developed Internet sites. Sites created by large international companies are more or less identical throughout the world. These sites not only offer product information but also quite often offer games, gadgets, and downloads that young people find appealing. On most sites, users must declare that they are over a certain age (e.g., 18 or 21) before entering the site. However, if adolescents falsely declare that they are older, they can enter as well. For example, in the United States the Center on Alcohol Marketing and Youth studied the age of the visitors of 55 websites of alcohol producers. Their data showed that 13% of the visitors of these websites were underage persons. These rapid new developments extend beyond national boundaries and therefore are outside the control of national regulations. So far, there are no international guidelines that have legal regulatory status.

AMERICAN ACADEMY OF PEDIATRICS

The American Academy of Pediatrics (AAP) is a professional organization of pediatricians committed to achieving the organization's mission of attaining "optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults" (2005; www.aap.org). It currently has 60,000 members. An essential way the AAP has fulfilled its advocacy role in recent years is through Media Matters, a national campaign dedicated to promoting awareness of media's impact on young audiences among other physicians, parents, and children.

The AAP was founded in June 1930 by a group of 35 physicians in Detroit, Michigan, who specialized in health issues affecting children. When the AAP was established, the notion that children have special developmental and health needs was new and progressive. Preventive health practices that are now associated with child care, such as immunizations and regular checkups, were only beginning to change the practice of treating children as younger versions of adults.

The AAP employs 350 individuals, supports 59 chapters in the United States and 7 in Canada, and works to educate and prevent medical and health problems worldwide. One way in which the AAP is able to reach beyond America's borders is through more than 1,000 international members from more than 60 countries, and the group has been able to establish connections with similar societies in Mexico, Brazil, and India. The AAP also publishes original research in social, economic, and behavioral areas and supports the funding of outside research endeavors relating to children's health and well-being.

One of the many functions that the AAP performs is making recommendations regarding the media's impact on children and adolescents. One AAP recommendation that has been the subject of much attention is its position that children 2 years of age and younger should not be exposed to any screen media, because the potential implications of such exposure remain unclear. In a 2004 study published by Gentile and colleagues, more than 8 in 10 pediatricians (84%) reported that TV watching has a negative effect on infants' and preschool-age (parallels *school-age,* per *Websters)* children's brain development, although the study also revealed that pediatricians are often unaware of the AAP recommendations and generally recommend that parents limit media use to less than 2 hours each day.

The Media Matters campaign was launched in 1997 and is intended to raise the public's consciousness about the influence of media (television, movies, computer and video games, the Internet, advertising, popular music, etc.) on child and adolescent health. The organization understands that a great deal of the information to which children have access comes from various media outlets and that the information children receive from media sources can impact their thinking on public health issues. Subjects addressed by this campaign include the use of tobacco, alcohol and other drugs; aggression and violence; sex and sexual exploitation; and obesity and poor nutrition. An essential component of this campaign is to teach the basic skills of media literacy and critical thinking about media as well as to encourage people to become more discriminating about their media use habits.

The AAP considers the role of the pediatrician a crucial part of children's lives in regard to education on health and safety issues. In an effort to educate associated pediatricians about the impact of media on the lives of children, part of the Media Matters campaign is dedicated to bringing awareness to pediatricians. Research has shown that the key areas of concern about which the AAP feels pediatricians can provide education are aggression and violence, substance abuse, nutrition, obesity and dieting, sexuality and body image, and advertising and consumerism. In this new role, according to the information the AAP provides to its members, it is important for pediatricians to "understand and confront how images and messages in the media affect the health and well-being of adolescents." The organization believes that, as experts on child and adolescent health, pediatricians need to be at the forefront of this issue.

In reaching the crucial goals of media literacy and education with children and parents, AAP believes that the first step is to build an awareness of the hundreds of media messages with which children daily come in contact. The development of critical thinking and viewing skills is crucial to the success of media literacy. The AAP, by bringing media education into the realm of health professionals, intends to help children, adolescents, and parents understand that all media messages are constructed for a purpose, that

media images shape people's understanding of the world, that every individual interprets media messages differently, and that the mass media industry is driven by powerful political and economic forces. Through this campaign effort, pediatricians will be disseminating media literacy information to parents and children and talking to families about their media usage habits.

Through the Media Matters campaign, another goal of the AAP is to bring media education into the homes of families. The AAP provides parents with materials and suggestions to help them bring media issues to the forefront in their homes. The AAP brochure titled *Understanding the Impact of Media on Children and Teens* suggests ways families can constructively promote media education in their homes, such as by setting limits on television time, making deliberate program choices and appointment times for using media, prohibiting television viewing at use at mealtime, and asking the right questions to help children become critical viewers and encourage productive conversations about media.

Ongoing education is a critical part of Media Matters. The AAP provides ongoing support for trainees as they work with parents, teachers, children, schools, legislators, and media to help people become media educated. The organization continues to offer workshops at its national meetings and at other organizations, such as the American Public Health Association, the American School Health Association, and the National Media Education Conference. Additionally, the Committee on Communications has developed a policy statement on media education that focuses on the public health impact of media and how the medical community can begin to address these areas of concern. The Media Matters campaign has generated numerous articles in national publications, such as *The New York Times* and *USA Today*, about its successful efforts to curb the negative effects of media.

ANIME

Anime, Japanese animated films, although technically similar to the child-oriented cartoon offerings of American animation studios, are distinguished by their adult themes and complex story lines. The word *anime,* sometimes written as *animé* to make the pronunciation clear, is a shortening of the English word *animation.*

The earliest Japanese animated films, which date from 1915, dramatized folk tales using traditional artistic techniques or imitated the pace and humor of Western cartoons. In 1937, under strict government censorship, animators were restricted to producing cartoons for military propaganda.

Following World War II, studios continued cartoon production. However, release of Osamu Tezuka's TV series *Astro Boy* (1963–1966), based upon his *manga* (Japanese comic book) series, transformed animation. The series' futuristic, action-packed story line, sparse graphics, and wide-eyed characters set the tone for future anime. Tezuka cited Disney's animations as his inspiration. The adventures of the boy robot *Astro Boy,* created to replace a scientist's dead son, were immediately popular. *Astro Boy* also became popular with American audiences. Following *Astro Boy,* Tezuka (who is considered today to be the father of anime) established animation as acceptable for all ages by creating ever more sophisticated stories with adult themes along with children's entertainment.

Anime are a commercial art form made for specific age groups, though most are for adolescents and teens. All genres found in live action films are used in anime, including children's stories, fairy tales, science fiction, fantasy, historical drama, romance, horror, paranormal, thrillers, and erotica and pornography. The most popular anime combine themes (action, romance, science fiction, etc.) and explore the shifting nature of identity in modern society.

Artistic styles vary widely, though anime studios generally have an established style that the artists follow. Fewer details and frame changes per scene

than most Western animation give anime a choppy feeling, though the artists make up for this by also including scenes with many more details and frames for emphasis.

From 1963 to the 1980s, most anime appeared on Japanese TV. In the 1980s, the introduction of video recorders allowed artists to create animation that did not conform to TV requirements for length, number of episodes, and costs. Popular titles were adapted to TV or film formats. Theatrical releases, half of Japan's film output in 1999, have higher production values. Anime that contemplates the fluidity of one's character in modern society and combines a science fiction, action, or romance motif have proven to be the most successful.

Many of the anime that followed *Astro Boy* replicated the series use of the science fiction genre, reflecting both society's fears about the destructive power of science and its positive attitude toward technological innovations. These stories were eclipsed by series that explored the problems of a technologically based society and by epics focusing on giant robots such as *Gundam.* (Originally introduced in 1979, *Gundam* movies and television series remain popular today.)

One aspect of anime that separates it from cartoons is reality. Heroes often fail or even die, sometimes without any apparent reason. Although this seems harsh, anime fans see it as reflecting real life, in which triumph and justice are not always accorded to those trying to do right and be good.

Though clearly set in an unreal landscape, Hayao Miyazaki's *Nausicaä of the Valley of the Wind,* released in 1984, contained themes of environmental destruction that led to its brief banning in some European countries. The film created demand for socially conscious anime in both Japan and the United States. The significant alterations made to the American release, which changed it from a dark story of ecological danger to a rather tame adventure story, also led to Miyazaki's insistence on "no-edit" clauses for future releases. Miyazaki's *Spirited Away* (2002) won the Oscar for best animated feature-length film at the 2003 Academy Awards, and his film *Howl's Moving Castle* (2004) set box office records when it was released in Japan.

American imports increased in the 1990s, with some on TV (*Sailor Moon,* 1995–1997; *Gundam,* 2001) and others on video or DVD. In 1998, *Ghost in the Shell* (1995) topped the *Billboard* video sales charts. Twenty anime series were broadcast on American TV in 2003. Some fans complain that editing to remove objectionable content, generally sex and violence, turns anime into cartoons; these fans prefer DVD releases, which allow selection of original, dubbed, or subtitled versions. Controversial is the prevalence of *fansubs* (fan-created subtitles) for bootleg series not released in America. Some fans decry this; others claim fan translations create demand for the DVD.

Most American fans are teens and college students. Many American fans consider Katsuhiro Otomo's *Akira* (1988), which graphically depicts government corruption and individual alienation in modern society, to best illustrate the genre's vitality.

Studies of anime suggest that it can play a positive role in a variety of literacies. A study of the impact of the Pokémon anime series, which was introduced on American TV in 1996, suggests that, far from being detrimental to learning and literacy, anime encourages an active, pleasurable learning experience that can help improve literacy. Studies also suggest that anime, along with manga, are a particularly rich source for the production of fan fiction by adolescents. Fan fiction, or *fanfic*, is genre of text production in which fans use popular culture to provide a starting point for their own stories. The construction of fan fiction, which is often written in collaboration, allows adolescents to learn to read texts more deeply and contributes to development of their literacy skills.

ANTI-DRUG MEDIA CAMPAIGNS

From the 1930s movie *Reefer Madness* to the 1980s "Just Say No" and "Cocaine: The Big Lie" campaigns to, most recently, the large-scale U.S. National Anti-Drug Youth Media Campaign, scholars, advocates, and critics have long pointed to examples of mass media content intended to curb adolescent drug use. These efforts stem in part from periods of intolerance for drug use that have existed in many Western societies and that have been fueled by more recent scientific data showing the harmful consequences of illicit drug use. Despite this collective attention to drug use, nonetheless, two questions remain open to debate: whether anti-drug media campaigns are effective and ethical, and how media content and drug use in general are linked.

ANTI-DRUG CAMPAIGNS: PAST AND PRESENT

Media-based campaigns to discourage drug use have been planned and implemented around the world, from Hong Kong to Bolivia. Many of the most prominent examples in recent years, however, have been based in the United States. Those efforts have differed in their use of media channels, in the degree to which campaigns have paid for placement of campaign materials, and in the extent of evaluation conducted. The Reagan administration's "Just Say No" effort in the 1980s, for example, was largely a public relations effort with no formal summative evaluation. In contrast, a large-scale campaign initiated by the Office of National Drug Control Policy in the late 1990s—the aforementioned National Anti-Drug Youth Media endeavor—included the use of major commercial advertising agencies to develop advertisements, the purchase of airtime and print space in a variety of high-profile venues, and formal evaluation by the National Institute on Drug Abuse and third-party researchers. On a different level, a host of state and regional media campaigns have been funded in recent decades in the United States, in addition to school- and faith-based programs, although we currently lack solid scientific evaluation of such campaigns.

These and other anti-drug media campaigns have tended to vary considerably in their use of communication theory and behavioral theory. Efforts such as the aforementioned "Just Say No" project offered simple admonition to children and adolescents to stay away from drugs. More recent efforts have attempted to incorporate behavioral models—such as value expectancy theories, which see drug use behavior as subject to the influence of a range of beliefs about the pleasure and utility of drug use, others' expectations about drugs, and one's own ability to avoid drugs—into campaign planning. On a different plane, some of these campaigns specifically consider the impact of placement and editing in light of media preferences that those likely to experiment with drugs tend to exhibit.

CAMPAIGN EVALUATION CONSIDERATIONS

Given the diversity of various campaign efforts, it is not surprising that, when campaigns have been formally evaluated, results have varied. We do not yet have sufficient evidence to declare that media-based efforts either always do or always do not affect drug use among children and adolescents. Some large-scale efforts (e.g., the National Youth Anti-Drug Media Campaign) have failed to yield persuasive evidence of impact, whereas some smaller, targeted efforts (e.g., the Two Cities Anti-Drug Television Campaign conducted in Kentucky and Tennessee) have shown evidence in favor of intended effects with specific audiences. As a result, answering the question of whether media-based drug use prevention campaigns directly discourage drug use is not a simple task.

What we do know is that certain patterns tend to plague campaigns intended to reach adolescents (and other audiences) and to complicate the evaluations of those campaigns. And there is consensus among scholars and practitioners that anti-drug campaigns, and media campaigns in general, often fail to demonstrate effects for multiple reasons. For instance, many campaign planners fail to conduct adequate precampaign (formative) research to collect the information needed either to design messages in a way that will address the audience's existing beliefs or to place the messages strategically in media where they will be seen, heard, or read by the target audience. Additionally, campaigns that do not identify a specific audience segment to which the campaign is most relevant often make the mistake of trying to get the message out to the undifferentiated masses. Instead, campaign planners generally agree that it is important to specify a target audience in order to design more effective and appealing messages. Campaigns for

specific groups of adolescents, for example, can ensure that campaign messages achieve widespread and frequent exposure among the target group of adolescents for a sufficient amount of time. Finally, evaluation design also has played an important role in shaping our knowledge on this question. To date, many evaluations rely on a pretest and a posttest to indicate the campaign's effectiveness. Such limited information, however, does not account for the secular trend of the behavior both prior to the pretest and during the campaign. Longitudinal data collection, well before the campaign starts as well as after the campaign ends, is typically a good solution for detecting both secular trends and the effects of the campaign. A control group is also desirable.

Beyond questions of evaluation design and analysis, in some instances media messages intended to discourage drug use also actually may activate or reinforce positive attitudes toward drugs, a reactance phenomenon sometimes labeled as a boomerang effect. The effect may surface when an adolescent sees or hears an ad that the adolescent feels threatens his or her choice to act autonomously. Similarly, a boomerang effect may occur among drug users who are presented with threatening messages about dire consequences that do not include any recommendations for avoiding the threat. Adolescents can and sometimes do process messages in a defensive—or at least a biased—manner.

EXAMPLES OF CAMPAIGN OUTCOMES

The National Youth Anti-Drug Media Campaign offers a good example of the mixed results in this arena. Despite the fact that the campaign remains somewhat of a benchmark for the design and execution of campaigns for adolescents and their parents, it has yet to produce substantial results that evidence its success in reducing adolescent drug use. Although teenage marijuana use decreased during the campaign, the campaign's evaluators have yet to associate the drop in adolescent drug use specifically with exposure to the campaign. At the same time, it also might be the case that the campaign did not produce a uniform effect: Indeed, independent studies suggest that some of the message frames were more successful than other message strategies with certain audience segments.

On the other hand, evidence that anti-drug media campaigns do work under some circumstances is provided in a television-only anti-marijuana campaign (the Two City campaign noted earlier) that specifically targeted so-called sensation-seeking adolescents. Sensation seekers are those who often seek out various thrill-providing activities to satisfy their higher-than-average need for stimulation. High-sensation seekers also appear to have very specific media preferences, often preferring media that contain graphic or intense images and sounds and that are arousing, stimulating, and fast-paced. By acknowledging these preferences, campaign planners in the Two City example developed multiple anti-drug ads with characteristics that should have appealed to high-sensation seekers and employed them in two 4-month campaigns in Lexington, Kentucky, and Knoxville, Tennessee. Longitudinal time-series analyses revealed significant drops in marijuana use among high-sensation seekers in both cities.

Underpinning the campaign in the Two City example is a strategy that has been formally labeled *SENTAR,* short for Sensation Seeking Targeting. The four principle steps of SENTAR are (1) segment and target the at-risk sensation seeking audience, (2) design high-sensation-value messages that are most effective with this audience, (3) purchase airtime, and (4) place messages in programming contexts mostly likely to be viewed by the target audience. Although SENTAR has been successful in anti-drug (marijuana and inhalant) television contexts, it remains to be seen whether the strategy is effective with other substances, such as alcohol or tobacco.

BEYOND CAMPAIGNS: MEDIA COVERAGE OF DRUGS

Prevention campaigns also do not operate in isolation and instead face a media landscape that is varied in its depiction of drugs, a fact that contributes to the difficulty that proactive efforts sometimes face in generating sufficient exposure for specific campaign messages. In the past century, for example, a variety of noncampaign sources have contributed to the American information environment with regard to drugs. The topic of illicit drug use periodically surfaces in the news, as evidenced by celebrity drug deaths or drug-related foreign policy stories, although the typical frames of such stories focus on the event at hand rather than larger themes, and such coverage often disappears as quickly as it appeared. Moreover, illicit drug use is sometimes depicted in television programming or other entertainment media, although the picture there has been an uneven one as well.

Content analyses suggest that illicit drug use, and especially use framed in a positive light, is not especially prevalent in contemporary broadcast television. At the same time, evidence also suggests that other outlets, such as music videos or movies, sometimes offer a more explicit and potentially more encouraging depiction of some kinds of drug use.

ETHICAL ISSUES

Despite the large amount of money that is often spent on anti-drug efforts, and the not-for-profit nature of such campaigns, questions have been raised as to whether such endeavors sometimes cross important ethical boundaries. All communication campaigns rest on certain assumptions about values, and drug prevention efforts are no exception. Two examples of ethical issues raised about media-based drug prevention efforts involve the selection of certain drug use as a target and potential unintended effects on addicted users and their interaction with society.

Critics worrying about the justification for contemporary drug prevention efforts sometimes point to the fact that at the same time that large-scale drug campaigns are funded, direct-to-consumer (DTC) advertising nonetheless invites consumers to view pharmaceuticals in general as potential solutions to life's problems. Changes in U.S. Food and Drug Administration regulations of DTC advertising in the 1990s, in fact, have led to an increased amount of such advertising on U.S. airwaves, including advertisements for lifestyle-enhancement drugs that trouble some. From a policy perspective, some argue that funding campaigns against illicit drugs and allowing DTC advertising are countervailing actions.

Some critics also worry that some methods used to discourage adolescents from trying illicit drugs, such as emphasizing the moral depravity of drug use, may portray those who are currently addicted to drugs as morally inferior or undeserving of treatment assistance. Such concerns raise important questions about the trade-offs involved in certain media-based strategies. These questions are especially important in light of the questionable efficacy of strategies that focus solely on negative consequences.

APPRECIATION INDEX

There are three widely known ways to appraise screen material, two of which are systematically representative of the public. For television programs and for movies, the size of the audience is estimated on the basis of representative audience methods. However, in several countries (the United Kingdom, Canada, Netherlands, Australia, and elsewhere) another systematically representative assessment method has been used and in some cases is still used: the measurement of appreciation. Movies and television programs are also awarded prizes (Oscars and Emmys); however, the prize juries, although influential and knowledgeable, are "invisible" and do not represent the public. Thus, this method of assessment is nonrepresentative (and thus potentially misleading).

In a democratic society, in which votes count as opinions, the box office and audience size measures are widely supposed to denote popularity or liking. Yet, many other elements, such as publicity, release times, and channels, also influence how many people see a work; thus, simple audience size is not an automatic index of merit. The faction that treats large audience sizes as simple good news consists of marketers and advertisers. For them, a good program is one with a large audience, which is why they support "the ratings" as measures of value; such ratings do measure marketplace income.

All this obscures an important dimension that has been measured in many countries by an Appreciation Index (AI), as explained by J. Mallory Wober in his 1988 book *The Use and Abuse of Television.* The AI—usually measured confidentially—is found by asking representative samples of the viewing public to rate each program they see on a scale. Currently, the UK system uses a scale from 0 to 10; the viewers who give an opinion for a program are a representation of its audience, and their marks are averaged and expressed on a scale from 0 to 100. Thus, the AI is a systematically represented evaluation of a program. There is much evidence that the AI is a reliable measure. At least two projects measured AIs for programs in the United States. The AIs in these U.S. projects (both now discontinued) were very similar to AIs for these same programs shown in the United Kingdom.

AI results show that some programs have small audiences and low appreciation and would find it difficult to survive in commercial conditions. Yet other programs have small audiences but high AIs, suggesting a value that has escaped assessment in the market. Such a program might gain a larger audience shown at some other time and thus be valuable to broadcasters; but it also points to a social value or public benefit that broadcasters in many countries have wanted to identify and sustain.

The *Encyclopedia of Children, Adolescents, and the Media* is likely to have a modest or even low level of circulation (a measure equivalent to the so-called program ratings in TV) compared with that of a Harry Potter movie; yet an assessment (or true *rating*) by a representative sample of its readers might reveal a score as good as, or perhaps even better than, that given by Potter moviegoers using a similar rating method. The two methods of assessment show some similarities in some situations but are more truly complementary and different. Both are useful and valuable, and the appreciation results should certainly be obtained where possible and not kept confidential.

Barrie Gunter and Mallory Wober found that, among early teen viewers in the UK, the categories of situation comedy and American and Australian drama series shown in the UK gained the highest AIs, with news and documentaries receiving much lower AIs. Viewers aged 16–24 showed similar likings, but documentaries were ranked higher. These priorities of appreciation are very different from those found among older viewers. For marketers, there is evidence that advertisements may themselves be evaluated differently depending on the AIs of the programs in which they are contained.

AROUSAL THEORIES

Arousal is a central concept in the analysis of moods and emotions, regardless of whether these experiences occur in actual social situations or are elicited by veridical or fictional media presentations. Although the conceptualizations of arousal show marked differences, some form of physical excitedness is consistently invoked as the primary determinant of the intensity of emotional experience and behavior. Much research attention has been given to the possibility of manipulating this intensity, especially in the context of media entertainment with its apparent agenda to maximize emotional experience. Theories of sensation seeking address the latent yearning for excessive excitement, especially among emotionally labile adolescents and young adults. Excitation-transfer theory, moreover, deals with the escalation of emotions, in particular with the exploitation of aversive emotions for the intensification of subsequent positive excitement, delight, exuberance, and exultation.

AROUSAL IN EMOTIONS AND MOODS

Arousal refers to the bodily condition of being roused, literally the experience of "shaking one's feathers."

In nonmetaphoric terms, being roused or aroused manifests itself in heightened overt and covert activity. Such states of acute arousal characterize all vital emotions, and the experience of these states is part of all strong feelings. Arousal is an essential component of pleasure and displeasure, sadness and happiness, love and hate, despair and elation, gaiety and dejection, rage and exultation, exhilaration and grief, frustration and triumph, merriment and fear, anger and joy, and other emotions of high experiential intensity. Although sexual activities are usually not included in the enumeration of emotions, they certainly have their place among acute emotions. The high arousal intensity associated with vital emotions is comparatively short-lived and is strongly focused on both causal circumstances and motivational implications.

Moods are considered affective states that are also associated with elevated arousal. In contrast to emotions, however, moods are characterized by lower arousal intensities that persist for longer periods of time. Additionally, whereas emotions are instigated by apparent causes and, in turn, instigate cause-determined actions, moods lack such focus and are marked by motivational diffuseness instead.

Individual differences in emotionality and moodiness can be pronounced, as can developmental differences. During childhood and adolescence, for instance, the control of impulsive emotions and lingering moods tends to be wanting, mostly because of developmentally lagging anticipatory and judgmental skills.

CONCEPTIONS OF AROUSAL AND ITS FUNCTION

In earlier theories of motivation and emotion, arousal was treated as a unitary force energizing behavior that receives direction by independent means. Behavior theory likened arousal to an engine that drives, but does not guide, overt actions. The necessary guidance was thought to come from impulses that, at any given time, were dominant in the habit structure, this structure being partly determined by instinct but mostly established through learning. Arousal or drive strength was not directly measured and thus remained a hypothetical construct.

Activation theory similarly construed arousal as the behavior energizer and held some form of cognition accountable for behavior guidance. In contrast to behavior theory, however, activation theory committed itself to measuring arousal strength. It focused on activities in the brainstem reticular formation. Measured in wave patterns and rhythms of the encephalogram, states ranging from coma through sleep, drowsiness, relaxed wakefulness, and alert attentiveness to strong, excited emotions were distinguished and used to map emotional intensity.

In a two-factor theory of emotion, Stanley Schachter (1964) adopted the apparent dichotomy of energization by arousal and guidance by cognition. As some of the research conducted in connection with the theory involved the injection of epinephrine (an adrenal hormone that activates sympathetic excitation), arousal was implicitly operationalized as heightened sympathetic nervous system activity. Following suggestions by William James, who had emphasized both the intero- and exteroception of arousal as emotion determinants (e.g., heart pounding or palm sweating, respectively), Schachter's theorizing focused on such feedback as indicators of the intensity of feelings and emotions. Specifically, Schachter argued that the awareness of being aroused, as mediated by sensations of bodily reactions, instigates an epistemic search for the reactions' causes and that the cognitive evaluation of the causal circumstances provides the comprehension of which particular feeling or emotion is experienced.

Dolf Zillmann proposed a three-factor theory of emotion that retained the distinction between energization by arousal and guidance by cognition. In order to account for the origination of arousal reactions that is left unaddressed in Schachter's two-factor theory, the guidance function was divided into a dispositional and an experiential component. The dispositional factor integrates ontogenetically fixed and acquired dispositions in explaining autonomic reactivity and the guidance of deliberate as well as impulsive overt behavior. The experiential factor entails the cognitive appraisal of prevailing circumstances, including the appraisal of bodily feedback. In case these appraisals indicate inappropriate reactivity, this factor functions as a corrective by redirecting overt behavior and, to the extent possible, by initiating the regulation of autonomic activity.

Three-factor theory incorporates Walter B. Cannon's (1932) conception of archaic emergency emotions. Cannon implicated sympathetic dominance in the autonomic nervous system with the function of providing energy for an episode of vigorous action as needed for fight and flight and, by extension, for sexual engagements. Although the conditions of modern life render most fight-flight reactions inappropriate, information about threats to personal welfare, or about opportunities for its enhancement, still generates strong arousal

reactions that, as evolutionary remnants, are meant to energize immediate emergency-resolving action. These strong arousal reactions become linked to all basic emotions and determine their behavioral intensity and the intensity of associated experiences.

Sympathetic arousal of both emotions and moods is thought to be controlled by brain structures integrated in the limbic system. The episodic versus tonic arousal supply of emotions and moods, respectively, is mediated by different endocrine mechanisms, however. The high excitatory intensity of emotions is primarily a function of activity in the sympathetic adrenomedullary system with its release of catecholamines. In contrast, the low excitatory intensity of moods is primarily mediated by activity in the pituitary adrenocortical system with its release of cortical steroids. Activity in the pituitary gonadal axis with its release of gonadal steroids is likely to assist the excitatory function of both these systems. But the intensity and duration differences between emotion and mood are by no means clear cut. Emotions may be repeatedly instigated and then amount to prolonged agitated behaviors and experiences. On the other hand, moods may give way to emotions or fatigue and thus terminate after brief manifestation.

THEORIES OF AROUSAL SEEKING AND MANIPULATION

The state of acute bodily arousal that accompanies intensely felt emotions is hedonically ambiguous and thus arbitrarily interpretable. Sympathetic arousal associated with acute anger, for instance, usually fuels an experience that is construed as unpleasant. However, the same arousal associated with triumph and exultation or with sexual activities can intensify experiences of genuine pleasure. Despite or perhaps because of this hedonic plasticity of arousal, its accumulation to extreme levels is often sought and the experience valued in its own right. Under the heading of excitement, intensely felt states of sympathetic arousal are often cherished as experiences of great pleasure. Adolescents and young adults, in particular, seem partial to seeking and taking pleasure from such extreme arousal states. Their obtrusive predilection has been attributed to increasing gonadal-hormone concentrations at the onset and during sexual maturation in concert with lagging prefrontal development. The changing hormonal conditions markedly heighten excitability, especially in young men whose androgen levels may rise up to twentyfold, whereas the still maturing central nervous system impairs the down-regulation of emotion, in large part because of a narrow focus on immediate gratification. Following adolescence, the belated maturation of the prefrontal structures is thought to enable appraisals of emotional reactivity that integrate situational, social, moral, and prospective considerations and thereby mitigate and compromise the unhampered escalation of excitation that characterizes the excessive emotionality in the preceding developmental stages.

Percy Tannenbaum (1980) considered arousal states in juxtaposition with boredom, a state characterized by minimal arousal levels, and suggested that essentially any jolt of arousal would be appreciated and hence preferred by persons living in a secure and dominantly hapless social environment. The premise that this precondition is prevalent in modern times might be questioned, however.

Marvin Zuckerman elaborated this consideration, arguing that humans, like other primates, are genetically prepared to cope with aversive conditions on a regular basis but that modern life deprives them of challenges, especially of physical challenges that would engage their innate abilities to protect and usurp. He focused on a need for stimulation, essentially an inclination to seek out challenges, as an individual difference variable in order to explain why some are more driven than others to jump from airplanes, climb cliffs, do drugs, or watch horror movies. In this conceptual framework, stimulation is attained for its excitatory quality and at times might even be deemed noxious throughout the experience. More likely is that challenging circumstances will come to an end and their termination, especially when brought about by effective coping maneuvers, can be expected to foster some degree of pleasure.

The transition from challenge to pleasurable reaction has led to proposals that make the intensity of pleasure partly, if not entirely, dependent on the intensity of preceding displeasure. Michael J. Apter (1992) invoked such a dependency. He distinguished zones of safety, danger, and trauma and proposed that nonrisky behavior in the safety zone is unexciting and humdrum; that risky behavior in the danger zone is exciting and enjoyable to the extent that trauma is avoided; and that risky behavior in the trauma zone, although exciting, causes harm and hence, if it is not fatal, displeasure. In this model, risky behaviors in the danger zone are the more enjoyable the closer they are to the border of the trauma zone. Prior risk maximization amounts to ultimate pleasure maximization, provided

the traumatic conditions are successfully negotiated. Playing it safe, on the other hand, is the formula for boredom because of the lack of arousal generation.

Apter has aggregated an impressive array of illustrations that seem to agree with his model. Car racing, roller coaster riding, rock climbing, hang gliding, bungee jumping, fugu (a highly toxic pufferfish) eating, juvenile wilding, and erotic scarfing are all considered demonstrations of the practice of pushing danger to the trauma edge in order to attain the most intense experiences of joyous excitement.

Apter's observations are consistent with the theory of excitation transfer proposed by Zillmann. This theory addresses the interdependencies between contiguous emotions and moods. More specifically, it addresses the intensification of affective reactions that occur later in a chain of reactions by residual arousal from affective reactions that occurred previously in that chain. The asynchrony between arousal processes and the cognitive appraisal of environmental changes is pivotal. Owing to the systemic hormonal mediation of sympathetic excitation, arousal reactions, once instigated, tend to outlast the emotions that were initially associated with them. In contrast, neurally mediated cognition can foster rapid comprehension of situational change and an adjustment to the new circumstances. The consequence of this time discrepancy in adjustment is that arousal from a prior emotion will linger when, by appraisal, it is superseded by another emotion; and given the hedonic plasticity of arousal, the lingering portions of arousal will combine with arousal produced by the new emotion and intensify this emotion. Most importantly, because arousal does not influence the hedonic quality of emotional experience, and because this quality is entirely determined by cognitive appraisal, the transfer of residual arousal can intensify hedonically opposite emotions. Arousal residues from unpleasant emotions can intensify pleasant emotions and vice versa.

Consider, for example, a woman who steps on a snake in the grass. The event is likely to instigate a strong arousal reaction along with evasive action. Consider further that it was a prank of her young son, who planted a rubber snake. Cognition reveals instantly that fear is groundless. Arousal, however, is just manifesting itself, and the woman is likely to tremble for minutes after the shock. During this period of residual excitation from fear, she is bound to react overly intensely to any emotion that her cognition dictates. She might feel abused, get angry, and overreact aggressively. On the other hand, she might feel foolish being angry and burst into hysterical laughter, exhibiting mirth to a degree that is entirely incommensurate with the safe sighting of a rubber snake.

Transfer theory, then, is capable of explaining the appeal of the extreme affect conversions from experiencing emotions such as fear and terror into emotions of great joy and elation upon surviving faced dangers unscathed. Crossing the hedonic divide from displeasure to pleasure need not involve extreme emotional reactions, however. In fairy tales, for instance, a degree of aroused apprehension about the welfare of a protagonist usually suffices in creating substantial euphoria upon a happy turn of events. The phenomenon of suspense in drama, sports, reality programming, and the news, as well as in the drama of daily life, generalizes this principal conversion. The appeal of media violence has been similarly explained as due to terror arousal that intensifies satisfaction with the justice-restoring heroics in concluding events.

The intensification of euphoric emotional reactions by residual arousal from noxious emotions is by no means the only affect transition that is open to manipulation by message sequencing. All conceivable transitions are. It has been demonstrated, for instance, that residues of pleasantly experienced sexual arousal that was induced by exposure to erotica can intensify reactions of acute anger to provocative revelations and ultimately facilitate aggressive outbursts. But it also has been shown that the embedding of sexually arousing erotic images in music videos can markedly enhance the enjoyment of music.

As the hedonic quality of mood also depends on the cognitive appraisal of the prevailing circumstances, mood changes are analogously subject to transfer enhancement. Although residual amounts of arousal from earlier moods may be comparatively small, they should nonetheless elevate the experience of different, newly materializing moods.

—Dolf Zillmann

ASIA, MEDIA USE IN

Children and young people are fascinating to work with because their tastes are so diverse and their needs so specific. This diversity means that we need to internationalize our understanding of young people and learn how to study them in ways that are relevant to their experiences and situations. Children in Asia are the focus of this entry, with an emphasis on how they fit into a wider story of media in Asia and its influences and conditions of existence. Children in Asia comprise varied populations, and their media use is therefore not easily characterized. This entry offers categories of description and delineation that may be helpful in approaching the study and understanding of a crucial sector of the global media audience for television, film, publishing, radio, and the Internet. It argues in particular that it is useful to examine the impact of economic development, evolving national identity, and other cultural forces on the experience of Asian children who are consumers of media.

Asia encompasses highly developed social entities, such as Singapore, Hong Kong, and Japan, as well as areas of extremely uneven development, such as China, India, Indonesia, and North and South Korea. Although Southeast Asia, South Asia, North Asia, and the Asia Pacific regions share trans-sectoral similarities as a result of history and geography, each also has distinctive characteristics. This complicates any attempt at continent-wide assertion or analysis. However, it does offer a first point of call for sketching out possible parameters of study and thought. Development is a key feature of governance in much of modern Asia. This derives from a need to catch up to and compete with the modernity and attendant wealth achieved during the late 19th and 20th centuries in the United States and western Europe. In the post-colonial period, considered here to be from the 1940s through to the 1960s (with a few later exceptions), the shift from a dependent and often premodern economy to an upscale and ambitious program is best seen in the Singaporean model. Colonial economies have often been left underdeveloped by their colonial masters, a situation that has inhibited the formation of modern media and communications systems. Thus, after independence, nations such as Singapore have needed to catch up and develop modern systems, structures, and economic identities rather quickly.

The focus on development has tended to be at the expense of more relaxed approaches to modern life, and media expression has been a casualty of this need to make change effective and efficiently. This “developmentalism” has led to a functional approach to media and, as national media have emerged in the wake of empire, their role was (and is) seen to support the accelerated growth of national sovereignty, wealth, and stability. It can be argued that, given children’s centrality to the future of any nation—and especially to those nations that are really new in the sense that they are reinventing themselves as independent economic and political entities on the global stage—development is a relevant perspective from which to examine Asian children’s use of media.

THE IMPACT OF DEVELOPMENT ON CHILDREN AS MEDIA CONSUMERS

Development and the media have been explored in scholarship on developmental journalism, particularly in relation to the Indonesian print media. The problem

underlying most of these discussions is how a national media may distinguish between necessary discipline in the construction of a sovereign entity and overly restrictive practices that curtail democratic aims and a free press. This argument is a useful starting point for looking at how children are understood as consumers and citizens in a media sphere. The core considerations might be as follows: Media regulation and content should support national priorities in a developmental economy. Education is almost always going to be one such priority, and therefore one might suppose that children's media might also be prioritized as a tool of social and cultural education. In practice, it seems that, although developmentalism is expressed in systems that differ greatly, all have a strong tendency to tie developmental policies to the ideologies of the central state. The result can be media that focus on education or media in which children are utterly forgotten. In Indonesia, where state ideology has referred to all people as "children of the nation," children themselves are not well served by media. In China—where children have been seen since the victory of the People's Liberation Army in 1949 as the successors to the nation, and where education is highly valued—there has been great emphasis on children's media needs. Developmentalism may also be an unspoken excuse for a total neglect of children's programming in an otherwise eclectic diet of nationalistic culture, religious epics, 24/7 news, and cricket, even when media are available in a number of local and national languages (as has been the case in India).

A very different scenario pertains to an already-developed economy, such as that of Japan, where there is a successful animation industry and where children's entertainment has—in tandem with adult counterparts in anime—become a marketable and valuable product both at home and overseas. In this case, the need for local content for an appropriate age level sits comfortably with the possibility of entertainment targeted at specific markets. Japanese children have led the way as consumers of mediated merchandise—one of the fruits of development.

INTERNATIONALIZATION

A second important area for concentration is the internationalization of children's television and film, an area that has been dominated by animation and merchandise and by American popular culture. Although Disney is important in Asia as it is globally, it has not captured the market. Japan's success as a media exporter has had an impact on Asia, and North and Southeast Asia in particular, where children are as likely to watch re-dubbed Japanese television shows as they are to be familiar with Disney, Children's Television Workshop (producers of *Sesame Street*), and any homegrown product. In China, for instance, patriotic Beijing primary school children were quite unhappy in 2002 to realize that their favorite cartoon shows on China Central Television were in fact Japanese products!

Internationalization is a contemporary buzzword in media studies, but it has been in progress for many years. As early as 1959, China and France supported a co-produced children's film, *The Kite*. However, it was the relationship in the late 1990s between Asian markets and the American blockbuster television show *Sesame Street*—a show that had blazed a trail in multicultural educational TV in the United States—that brought the idea of global Asian consumers to the fore. This iconic moment coincided with Disney's careful negotiations with Chinese state authorities to ensure airplay for their classics and space for their merchandise in a bid to build a new generation of faithful fans. At this time, it is unclear whether the efforts of Disney will work in the long run. Chinese consumers have in general quickly tired of the purported glamour of international luxury goods production. Furthermore, "creative China" is becoming an urban mantra for Chinese media development, and, as Michael Keane's work on creativity suggests, it is doubtful that international incursions will survive without strong efforts at co-production and localization. Being foreign in Asian markets is not a good business model in the long term.

LOCAL CONTENT AND SOCIAL PLANNING

A third way in which children's media use is likely to throw up interesting paradigms for study is in the forms of local content and social planning. In Malaysia, to take one post-developmental situation, there has been a noticeable movement toward the Islamicization of everyday life over the past 5 years, as shown, for example, in the demonization of non-religious teenage activities. In Malaysia, some teenage activities, such as heavy metal music fandom, are tied explicitly in the press to Satanist beliefs and cults. Of course, this music is also critiqued elsewhere, but the difference here is that arrests are made and bands disciplined on the basis not of antisocial behavior but

on the grounds that such music is antireligious and is leading young people astray. To date, there is a minimal scholarly coverage of what this might mean for a children's media sphere, except that strictures applied to adult publishing are likely to include children's books and shows. For example, *3R's (Respect, Relax, Respond),* a TV show on teenage issues that is screened in Malaysia, is somewhat protected by the patronage of former prime minister Mahathir Mohamad's daughter but still is affected by censorship on issues of religion and morality. In 2004 and 2005, episodes with women dressing as men in short drama skits on dating, references to the use of condoms and to marital and premarital sex, and positive allusions to lesbianism were pulled. This is an interesting phenomenon in children's media that invites comparison with other trends across the world. For example, the children's film *Narnia: The Lion, the Witch and the Wardrobe* (2005) was prereleased in special nontheatrical arrangements to evangelical Christian churches in the United States and Australia in an imitation of the successful use of this strategy for the adult film *The Passion of the Christ* (2004).

The rise of religion in the media may mark a new stage in children's media use that will be alarming to secular parents, and the ways in which this may further divide and classify the Asian market will be important. It is a workable hypothesis, therefore, that state and religion will either collide on a transnational scale or collaborate with the commercial producers in making media regimes more religious, more nationally compliant, and more global as powerful belief systems and media empires get together in search of the next generation.

Now, the other narrative that challenges this story is that of the rise of the *prosumer*, a term coined by Stuart Cunningham at a forum sponsored by the Academy for the Humanities in Canberra, Australia, in 2005. A prosumer is an online child who surfs freely and uses the media not just to consume but also to show creative literacy through interactive software, design tools, and in conversations with people and ideas at his or her own desktop or wireless-enabled laptop. *Creative literacy* is a key concept deployed by the ARC Cultural Research Network in Australia to describe active consumers in a productive relationship with the media industries, particularly interactive software. The prosumer sidesteps the mass-produced product and makes his or her "own" content. This antidote to sophisticated indoctrinations is highly suggestive but is not likely to apply as a necessary example of liberatory prosumerism if we apply it to many Asian economies and regulatory regimes. After all, media consumers can download only what is available within the firewall created by the media regime in which they live and within the context of their income, their education, and the cultural possibilities of their own upbringing.

Although some researchers are skeptical about the extent to which prosumerism affects the media use of young people in Asia, there is evidence in China that young teenagers' use of the Internet for group chat rooms and the exchange of information ties them to larger affective generational groupings that challenge institutional controls at the level of family, education, and the state. In a survey conducted through the Chinese Academy of the Social Sciences by the Young People Research Unit, children noted that they loved the Internet because it helped them make friends. Of course, making friends is not a necessary precursor to innovative use of the media, but it does point to a new ease in a virtual communicative sociability that will enliven political possibilities in the long term.

The effects of media on young people are not necessarily political, however. Much of the Western debate on effects has concentrated on how media violence confuses and misleads children. This is a valid area of inquiry, given the extreme desensitization made possible not just through Hollywood aggression and the games industry but also by the evening news. Yet, a Western perspective should acknowledge that much activity has been prompted by the effects of adult violence in the real world on children's behavior, with adults taking only mediated responsibility for the outcomes. In other words, mediated fantasies of violence may be blamed or even scapegoated for antisocial behavior in the young, when perhaps domestic gun cultures and sanctioned state aggression at home and abroad may also be appropriate sources of concern. This is less of an issue in Asia, perhaps because the separation of real and imagined violence is differently understood. Although there is violence in Asia, as everywhere else, it is not yet usual to blame television or movies for its prevalence among younger people. Fantasy is understood as fantasy and is discussed in those terms. Historical violence is not thought of as problematic either, and connections are not made between a street brawl and a war film. Japanese anime is violent but also highly stylized, and the only violence on Chinese children's television is seen on reruns of revolutionary (and usually rather out-of-date) films.

Media effects as a concern in Asia are not couched mainly in terms of violence, but the concern is nonetheless expressed in relation to the effects of excessive advertising on children. Not much regulation exists in Asia specifically to protect children from the blandishments of food merchandisers, toy manufacturers, and the like, and—as the child market becomes richer and more easily targeted through specific programming—advertising and its putative effects on children's consumption are likely to increase.

The current field of study in children's media and communications has been greatly assisted by the work of the Asian Media Information and Communication Centre (AMIC), a Singapore-based Asia research communications center whose impact on the regional field continues to be substantial. AMIC has insisted on acknowledging the specific and local issues in the study of media in Asia and has brought together experts in communications across the region for conferences, publications, and debate. The group has taken up such important issues as children's Internet usage, children's media access, and children's social education. Arguably, their work has inspired international presses to take Asia seriously as a regional player in the world's media. The other important sources for potential study are the market research agencies, state statistical bureaus, and Web indexes of the merchandising sites.

Determining the number of children who go online, watch television, buy media-related merchandise, further their educations through distance learning programs, or use other media resources is an expensive project. Such information is valuable to industry because Asian children with access to media are a valuable and increasingly affluent target market. However, scholars in the media field also need to pay attention to those who do have neither access nor disposable income. Many millions across the continent—the rural poor, those dispossessed through class, caste, or gender—are not counted, and it is their differentiated media use, their truncated communicative opportunities, and their diminished possibilities of individual and communal development that should concern scholars of the field.

ATTENTION-DEFICIT HYPERACTIVITY DISORDER (ADHD)

The idea that television viewing shortens children's attention spans has been advanced for some time. References to the television as "the idiot box" or "the boob tube," or to children becoming zombies in front of the television, have popularized the notion that exposure to television inhibits children's ability to concentrate. Do these popular conceptions have any merit? Does television really lead to poor concentration, and, if so, what is it about television that causes such problems? This entry examines how television might influence the way the brain develops from the earliest ages and what role this influence has on children's capacity to pay attention. A number of studies have found an association between television viewing and attentional problems; however, few of these are

experimental studies. Data supporting the hypothesis that television viewing can shorten children's attention spans are inconclusive but highly suggestive, but ongoing research will hopefully clarify the relationship.

THE RISE OF ATTENTION-DEFICIT HYPERACTIVITY DISORDER (ADHD)

Over the past 20 years, there has been a tenfold increase in the diagnosis of attention-deficit hyperactivity disorder (ADHD, or sometimes just ADD), and it has become the most common behavioral problem in the United States, currently estimated to affect somewhere between 8% and 12% of children. Whether this increase represents a true increase in frequency of occurrence of the disorder or merely reflects an increase in its recognition is not known, but it almost certainly involves both. Some have hypothesized that the increasing use of television by younger and younger children has contributed to the rise in the prevalence of attentional problems. These concerns date back to the early 1970s and were based largely on anecdotal experience with little scientific backing. In summary, the data that television viewing can shorten children's attention spans is inconclusive but highly suggestive. It is hoped that ongoing research will clarify the relationship, but in the meantime, parents should minimize the amount of television their children watch in the first 3 years of life.

THE CRITICAL FIRST 3 YEARS

The first 2 to 3 years of life are critical periods for the development of young children's brains. During this time, the connections between brain cells (neurons) form at a very rapid pace. These connections, or synapses, can be thought of as the wiring of the mind, and they form the basis for the processing of thoughts. Consider that the average newborn human brain weighs about 333 grams. By age 2 years, it has tripled in size and weighs almost a kilogram. By age 7, it weighs about 1,200 grams, or 90% of the size of an adult brain. This rapid growth, especially in the first few years, happens in response to external stimuli. When we are born, our brains are not fully developed. Because the fine tuning in brain development happens outside the womb, it can be maximally adapted to the world in which we live.

Scientists have shown that newborn rat pups exposed to different levels of visual stimulation have dramatic differences in the architectures of their brains. In fact, if they are not exposed to light for a long enough period of time after birth, they will be permanently blind. Thus, there is reason to believe that the types, frequencies, and intensity of early stimulation may have profound affects on the developing minds of infants. Given the fact that young children spend more time watching television than in any other single activity besides sleep, there is ample opportunity for television to exert a powerful influence on those developing minds.

TELEVISION VIEWING AND ATTENTION

One of the central ways television succeeds in maintaining the gaze of very young children is through the *orienting response*. First described in 1927 by Ivan Pavlov (best known for his work with dogs), the orienting response can be thought of as the "What's that?" reflex. Simply put, it is a manifestation of our brain's keen interest in something new or unexpected. It is easy to see why this is (and more importantly was) critical to humans' survival. A new sight or sound could be a sign of imminent danger, and the human brain evolved to give that input instant, undivided attention until it could be reassured that the new stimulus did not pose a threat.

Consider now how television might affect this rapidly developing newborn mind that is conditioning itself—truly building itself—in response to the world around it. In contrast to the way real life unfolds and is experienced by young children, television portrays rapidly changing images. Lights flash, sounds blare, and scenes change. The orienting response keeps young viewers transfixed, even though they do not understand the content at all. Parents report that their infants and toddlers love *Baby Einstein* programs, but what they mean is that they watch it intently; they are mesmerized by it.

The concern that this high level of stimulation might adversely affect developing minds led the American Academy of Pediatrics to issue a statement in 1999 stating that children should not watch any television before the age of 2 years. That recommendation was criticized at the time because many felt that data were lacking to support their contention of harm.

TELEVISION VIEWING AND ATTENTION SPANS

Repeated studies have found that children with shorter attention spans watch more television than children

with longer attention spans. This is not surprising to the parents of any child with a diagnosis of attention deficit disorder, who commonly observe that television is the only activity on which their child can focus. Such studies tell us little except that there is an association between television watching and short attention span. It may be that television causes short attention spans, or it may be that watching television is soothing to children who already have short attention spans.

There have been a few experimental studies that have led to conflicting conclusions about the role that television may play in attention spans. The first study, done in 1973 by Lynette Freidrich and Aletha Stein, randomly assigned preschool children in a summer program to one of three television regimens, each of which entailed watching a given show 3 times a week for 4 weeks. The first group watched *Batman,* the second group watched *Mr. Rogers' Neighborhood,* and the third group watched other nonviolent programming on commercial television. After the study period, research assistants observed the children in a simulated classroom environment. Children who watched *Batman* were noted to have considerably less tolerance for delay. A subsequent study conducted by Dan Anderson and colleagues in 1977 randomized preschool children to one of three conditions: fast-paced *Sesame Street*, slow-paced *Sesame Street*, or being read to by a parent. The fast- and slow-paced shows were created by culling fast (or slow) segments from several episodes and splicing them together into a single 40-minute episode. Afterward, children were again observed, and their ability to resist impulsivity was formally tested. In this study, although the children in the fast-paced group showed more impulsivity and more diffuse and less directed play than the children in the book group, these differences were not statistically significant.

In another study (2003), Eugene Geist and Marty Gibson randomized children to (a) watch *Power Ranger*, (b) watch *Mr. Rogers' Neighborhood,* or (c) engage in age-appropriate play. Again, children were observed after they had spent 30 minutes in one of these activities. In this experiment, children who watched the *Power Rangers* had shorter attention spans than those in the other groups.

How does one interpret what seem to be conflicting studies? First, these are small studies that involve very few children. In statistical terms, this hampers the ability of researchers to detect whether any differences are actually present. Imagine that you were asked to determine whether boys in high school are taller than girls, and you were allowed to measure two of each sex. Although boys in this age range are, on average, taller than girls, with so few in your groups, by sheer coincidence you might fail to detect such a difference. In fact, you might even come to the opposite conclusion. For this reason, studies involving small numbers of children are said to be underpowered and should be treated with caution.

The second major caveat to bear in mind when interpreting these studies is that they were conducted in experimental conditions and on select populations. In other words, the people who participated may not be like other children, and the conditions under which they watched television (and, for that matter, played) may not be similar to other, more naturalistic environments. Moreover, if the true effects of television occur over long periods of time and with repeated exposures, then effects may fail to be detected in such short experiments, which typically last an hour or less.

Third, the nature of the shows that were studied varied tremendously. Commercial programming and public programming may be different in ways that explain the disparate findings. Perhaps it isn't *all* television that affects children's attention, but only certain kinds of television. Or perhaps one would need to expose children to more than 30–40 minutes of television to show significant effects. One final problem may be that the age of the children studied was the wrong age to be looking at. Perhaps, as we noted earlier, the effects of television are more pronounced (and more deleterious) during that critical window of brain development that occurs during the first 3 years of life.

Dimitri Christakis, F. J. Zimmerman, D. L. DiGiuseppe, and C.A. McCarty looked at the correlation between attentional problems and television exposure in a 2004 study of 1,354 children. When each child was 1 year of age (and again when the child was 3 years of age), his or her mother was asked how much television the child watches on a typical day. When the child reached age 7, the mother was asked a series of questions about her child's ability to pay attention, including whether their child has difficulty concentrating or is easily confused, impulsive, or restless. These are some of the core symptoms of ADHD. However, the researchers did not have data on formal ADHD diagnoses, which require input from both parents and teachers.

The study found that, for each additional hour of television that children watched on average during the first 3 years of their lives, their chances of having level-of-attention problems consistent with ADHD

increased by 9%. Put another way, a child who watched 2 hours of television a day before age 3 would be almost 20% more likely to have attention problems at age 7, compared to a child who watched none.

The strengths of this study were that it was large, it was nationally representative, and it used data on television viewing at very young ages. However, because the study was not experimental, that is, because children were not randomly assigned to watch more or less television, it is not possible to be certain that watching television *caused* their attention problems. Indeed, it is possible that the children with attention problems at age 7 already had them at age 1, that they were more attracted to the television, and that their parents indulged that interest by allowing them to watch more than other children.

B

BEDROOMS, MEDIA USE IN

The bedroom has long been a space in which children and adolescents both retreat and socialize, articulate maturity, and construct identity—and often all by negotiating the discourses of mass media. Whereas children may view their bedrooms as spaces for utility (to play, dress, and sleep, for example), adolescents treat their bedrooms both as safe havens from a world they are only beginning to negotiate as adults and as spaces in which they often have complete control over their surroundings and behaviors. The bedroom is often an adolescent's only private space, and the bedroom doors of teens often are marked with "Keep Out" signs. Conversely, the bedroom can function as a meeting space for socialization among peers, where friends may gather to listen to music, hover over a computer, or simply chat about their lives.

While a child is under the age of 10, the decor and design of his or her bedroom is largely determined by the parents, but from early adolescence on, teens use the walls of their bedrooms in large part to articulate identity and express personal creativity or cultural conformity. Television and film media have latched on to this idea, for example, by taking audiences into the carefully crafted bedrooms of Wally Cleaver of *Leave It to Beaver*, with its model airplanes and pile of homework, and of Seth Cohen of *The OC*, with Seth's homage to favorite band, Death Cab for Cutie. Even *The Brady Bunch* centered entire episodes around bedroom decor as Greg and Marsha Brady hung beads and carefully placed peace signs in their rooms—symbols that they were too old for the rooms of their siblings (which were filled with sports paraphernalia and stuffed animals and dolls) and that they were members of early 1970s culture.

Adolescents' rooms constitute cultures of their own, often rife with symbols of their occupants' gender, age, and generation; but, at the same time, they function as personal spaces in which teens may experiment with decorative taste and individuality. Adolescents use the walls of their bedrooms to continuously construct and articulate identity as they move into adulthood. Their statements of identification depend largely on the mass media and on adolescents' perceptions of what *should* be on their walls and shelves. These perceptions are largely dictated to them by the television shows and movies they watch, as well as the music they listen to (media activities that often take place in the bedroom, interestingly). This may mean carefully placed advertisements of scantily clad models from Abercrombie & Fitch placed next to a favorite childhood stuffed animal, and loud rock music blaring from speakers with childhood soccer trophies on top of them.

Conversely, as adolescents actively construct themselves by what they place on the walls of their bedrooms, their private use of media in the bedroom arguably also shapes their hopes and fears for their lives. In the bedroom, teens often experience media alone, so the media tend to weave together the private and public sides of adolescents' attitudes and identities.

As a station for more active media use, the bedroom is very much an epicenter of activity. As in ages past, the bedroom is a place to retreat to read books, both for school and pleasure, and to flip through the latest magazines. It is a time when youth back away from sharing media with the family—such as getting

together on the sofa to watch a favorite television show—to privately and individually consuming media, especially if it is possible to do so in the sanctuary of the bedroom. Through this solitary media use, adolescents may be better situated to cultivate more self-reflective, private personas. The imagery, words, and sounds with which they surround themselves help them make sense of their lives and can offer a sense of stability in their sometimes-turbulent lives.

There are plenty of opportunities for this process of private self-cultivation to take place at this particular time in history, for the 21st-century bedroom is a center for entertainment and technology. According to a recent survey of children and teens between ages 2 and 18, 71% of those surveyed had television sets in their bedrooms. In fact, one in four preschoolers claims to have TV sets in the bedroom. Thirty percent have VCRs or DVD players. More than a third of these have cable or satellite connections in their bedrooms, and 20% subscribe to premium cable channels. Thirty-nine percent have video game equipment in their bedrooms, where they can play the latest games either alone or with friends. Twenty-six percent of adolescents go online daily from computers in their bedrooms. Once online, they may sit in their rooms for hours, sending instant messages to friends, playing games, or buying clothing, and many still talk on their family's land-based phone lines or exchange text messages with friends from their cell phones as well.

As many parents will attest whose children blast their favorite bands as soon as they slam their bedroom doors closed, music continues to be an important factor in adolescent bedroom culture. As many as 84% of 8-to-18-year-olds' bedrooms contain radios, and 86% contain CD or tape players. Moreover, 61% of young people also own portable CD or tape players, and 18% (and increasing all the time) have portable digital music or MP3 players such as iPods that may be listened to on headphones while doing homework, hooked up to speakers and amplified, or carried along when they leave their homes. When both bedroom and portable music devices are combined, 95% of 8-to-18-year-olds have personal sources of music that they access.

The cultural site of the bedroom is seen by many as an important place, both for private time to negotiate identity and as a shared space where children and adolescents may socialize with friends away from the watchful eyes of their parents. And although this space may work as a center for resistance (often against parents and other authority figures), some researchers have raised questions about whether too much media in the bedroom is harmful. A study by the John Hopkins University Bloomberg School of Public Health and Stanford University that looked at more than 400 8- and 9-year-olds found that children with TVs in their rooms scored 8 points lower on math and language arts tests and 7 points lower on reading tests than children who did not have televisions in their bedrooms. Overall, children with bedroom TVs watched an average of nearly 13 hours of television per week, compared with an average of less than 11 hours per week among those without bedroom televisions. It was thought that lack of sleep caused by watching television in bed late into the night may be to blame for the pupils' poor performance; however, the study found that having a home computer had the opposite effect. Those with access to home computers scored around 6 points higher on math and language arts tests and 4 points higher on reading tests. In addition, the Internet proves to be an important social tool in the lives of children and adolescents. Many are able to use it to maintain psychological closeness with friends who are at a distance, but they also use it to manage the social worlds within which they move as they send IMs and emails to their friends from their rooms.

Furthermore, some parents express concern about adolescents and children who spend too much time in their bedrooms using media, and often restrict their media use there. Parents of older adolescents tend to have fewer viewing rules for television, but most children and younger adolescents report parental controls over the amount of time they are allowed to spend watching TV and the content of the programming. Parents are also increasingly vigilant regarding their children's computer usage. For example, in research reported from the Pew Internet & American Life Project, 61% of parents said they monitored their children's online activities, and 70% required them to use a computer in a "public" space in their home, such as the living room, kitchen, or den. These parents worried that their children would be approached online by sexual predators, but others simply did not feel their children and adolescents were mature enough to make sense of much of the information (especially the pornography) on the Internet. Unsurprisingly, research also shows that children who are allowed to have personal media in their bedrooms (including television, radio, and the Internet) also have fewer parental controls over the time they spend with media and over the content of that media.

Adults often worry that having too much media at one's disposal may be harmful in other ways. A body of research based on cultural studies of children and adolescents examines the media as a site where they negotiate attitudes and develop beliefs about gender, race, sexuality, and beauty ideals. Biologists and social scientists also cite the media as an influence on brain activity and biological development. Studies of families with more than two television sets, specifically families in which one of the TVs is placed in a child's room, have shown that children and adolescents who have their own television sets tend to negotiate mediated messages differently from those who share one television set with the family and negotiate the messages with other family members.

Worry is widespread that children and teens may be inundated with too many media messages and too many options for personal communication and entertainment. Another recent study found that 26% of children and adolescents aged 6 to 14 use varied media simultaneously. Although this multitasking may be viewed as evidence of children's sophistication and ability to accomplish more work than past generations, it also is viewed as symptomatic of a generation of youth with short attention spans who are unable to function productively without saturating themselves with media.

However, it is suggested by some that adolescents might have more control over media in their bedrooms than almost any other place they venture, because their bedrooms are their personal domains in which they determine what surrounds them and how they make sense of it. In this view, children and adolescents' interactions with media represent a dialectical process in which media are both amplified and restrained by them. They use their own lived experiences and embodied knowledge to understand the media as a cultural product; they select it, interact with it, and apply it in concrete ways in their everyday lives rather than let the dominant discourses and messages of the media dictate specifically how they feel and act.

It should be noted that young people's media usage in the bedroom varies by race, class, and the educational level of the parents. For example, children whose parents who completed high school or received a general education degree with no further schooling were more likely to have TVs, DVD players, and video game consoles in their rooms, whereas those whose parents had college degrees were less likely to have these media in their rooms. Also, far more young people from lower-income homes report having televisions in the bedroom than do those in middle- or upper-income groups. However, in general, children and teens from homes with incomes above $75,000 have access to more media, especially computers and the Internet. Teens who remain offline and do not have computers in their bedrooms (or homes) often are identified by lower levels of income and limited access to technology, and they disproportionately identify as African American. Furthermore, how children and adolescents understand and react to media in the bedroom also varies by race, class, and gender.

BODY IMAGE, ETHNICITY/RACE AND

Extensive research has linked adolescent media use with body image, typically finding that greater exposure to media representations of the thin ideal is associated with worse body image. Most of this research, however, has been conducted with samples that are exclusively white and female. Recent research exploring the role of

race and ethnicity in the relation between media use and body image has considered how adolescents of color might interact with media images somewhat differently from white adolescents, and how media images convey race-related information about beauty and bodies. Findings indicate that, in some cases, girls of color may be resistant, but not immune, to the detrimental effects of media exposure.

The media have frequently been implicated in the preponderance of body image concerns among adolescents, particularly adolescent girls. Research with white adolescents typically finds that, the more a girl watches television or reads popular magazines portraying the thin ideal, the worse she feels about her own body and the more she aspires to having a thinner one. Recently, scholars have questioned whether these connections would look the same among adolescent girls of color and, indeed, have cited two specific reasons for expecting that they would *not.* First, comparison studies typically find substantial ethnic group differences in body image outcomes. Specifically, relative to white girls, body image disturbances are fewer among African American girls, comparable among Latina girls, and greater among Asian girls. Second, analyses of media images reveal that, in addition to being thin, the mainstream beauty ideal represented by the media is almost exclusively white. Women of color are severely underrepresented on television and in magazine covers and advertisements; those that are included typically have European hair, skin tone, and features. Accordingly, two arguments have been put forth: One argues that girls of color might be protected from the adverse effects of media use; the other argues that they might be at even greater risk than white girls.

Empirical research supports both arguments, although the bulk of this research has been conducted with African American samples. Qualitative data suggest that, compared to white girls, African American adolescent girls resist mainstream media images, describing them as more unrealistic and irrelevant. Although white girls also acknowledge that thin-ideal media images are unrealistic, they believe the ideals are endorsed by people around them and accordingly strive to meet these ideals. African American girls, on the other hand, report rejecting the images as both unattainable for themselves and unimportant to others in the black community. Instead of turning to the media to define the body ideal, these girls turn to family, friends, and boyfriends. Moreover, they report comparing themselves not to white women on television but to black role models and women they know. Although these social comparison processes have not been directly explored among Latina adolescents, focus groups with Latina young adults yielded similar results. Latinas reflecting on the role of media in their development acknowledged that the ideal presented by mainstream media is restrictive, but they argued that they had other outlets for learning about healthier body ideals, specifically their communities and Spanish-language media.

Minimal empirical work has explored associations between media use and body image specifically among adolescents of color. In one study, television viewing was associated with increased bulimic symptomatology among white adolescent girls but not among African American girls. In the same study, however, comparison with and idealization of media images were associated with body image outcomes as strongly among African American girls as among white girls. These two findings suggest that African American girls may be somewhat protected from media's harmful effects relative to white peers but may still be at risk for body image concerns.

Recent work suggests that it may be useful to consider the diverse media offerings to which adolescents of color are exposed. Indeed, certain networks and genres are specifically marketed to African American or Latina/o audiences and largely feature African American or Latina/o characters. These media outlets may provide children and adolescents of color with messages about beauty, bodies, and the feminine ideal that are wholly different from those presented by mainstream media. Indeed, young Latinas report that, in adolescence, they turned to Spanish-language media for representations of a larger body ideal than were available in mainstream media. Accordingly, the impact of these diverse media outlets may not be uniform. Retrospective survey data have documented associations between the body satisfaction of African American undergraduate women and their television viewing habits during high school, finding that these associations varied with the genre of television consumed. Specifically, findings indicate that the viewing thin-ideal images of white women may be unrelated to the body image of African American adolescent girls. Furthermore, regular viewing of black-oriented television may be associated with *healthier* body image among African American girls.

Currently, no comparable research exists examining the role of media in the body image development

of boys of color, nor examining these processes in girls of other ethnic groups.

BODY IMAGE IN BOYS AND YOUNG MEN

Body image problems and disorders traditionally have been associated with girls and women, and the existing literature has focused on adolescent and young girls. This may be due to the fact that most males do not admit or acknowledge that they have problems or issues with their personal body images. Moreover, the literature that does exist on males and body image is inconsistent and sporadic. Yet, in recent years such issues among males have become more prevalent, and researchers have begun to focus on males as subjects of body dissatisfaction.

Defined as "a multidimensional construct that represents how individuals think, feel, and behave with regard to their own physical attributes" (Muth & Cash, 1997, p. 1438), body image involves two components: (1) body image evaluation, identified as the evaluation of an individual's thoughts and beliefs about his or her physical appearance; and (2) body image investment, identified as behaviors an individual performs to manage or enhance his or her physical appearance (Cash & Szymanski, 1995). According to the American Psychiatric Association, body dissatisfaction is *not* defined as the inability to accurately perceive one's figure or body size, nor is it defined as the connection between physical shape or size and self-worth; these are definitions and symptoms of eating disorders. Rather, body dissatisfaction consists of negative feelings or attitudes about these characteristics.

Such discontent is becoming more prevalent among adolescent boys and young men. Research has shown that 50% to 70% of teenage boys want to change their body sizes or shapes. Males who are involved in athletic activities, who are struggling with sexual identity, or who are overweight or obese are more likely to experience body image and dissatisfaction issues. Generally, underweight and athletic boys desire to "get bigger" or increase muscular density, whereas overweight boys desire to lose weight. This is different from adolescent girls, who strive for slimness and weight loss. Additionally, although a high percentage of females are dissatisfied with their body shapes, such dissatisfaction among boys is less common and appears to be unrelated to body weight. Females are typically unhappy with the lower body, whereas boys are more dissatisfied with the stomach.

In terms of athletics and body image, boys and young men involved in sports in which lean and smaller body types are preferred typically also have higher levels of body dissatisfaction. The most common sports that concentrate on body weight and size are wrestling, swimming and diving, track and cross-country running, cycling, and gymnastics. These activities place a high priority on low body weight and low body fat, leading some male athletes to engage in dangerous behaviors, such as laxative use, excessive exercise, calorie and fluid restriction, self-induced vomiting, and starvation, in order to achieve a set weight or qualify for a specific weight class. Such expectations lead adolescent boys and young men to internally compare their actual body sizes and shapes to the ideal physique; the discrepancies cause distress and body dissatisfaction. A 1997 study by Parks and Read found that adolescent football players were more satisfied with their bodies than adolescent cross-country runners were. The researchers stated that this difference could be because the body images of football players were closer to the mesomorphic male ideal.

Although considerable research has placed a spotlight on society's ideal for the female form, little research has been conducted on the possible ideal body for males. Murray, Touyz, and Beumont tested for the male ideal and found that 72% of the male and female research participants believed that society has an ideal body shape for males. The participants were then asked to elaborate on the ideal; 74% stated that the ideal was of a muscular form, whereas only 8%

stated that it was slim. Another study, from Thompson and Tantleff, focused on muscular and slim body shapes and asked participants what messages each represented. The muscular form was seen to be more assertive, sexually active, confident, popular, and athletic, whereas the slim figure was seen as lonely and depressed. Such assumptions about specific male forms are perpetuated or enhanced by current fitness and health magazines, which depict the strong, muscular, "six-pack abs" prototype on the cover and throughout the magazine.

Adolescent boys and young men are bombarded with as many messages and visuals of ideal body types as women are. Ideals are plastered on magazine covers and on the television and movie screens, and expectations are verbalized by parents, coaches, girlfriends, and peers. Other studies, from Sommers-Flanagan, Sommers-Flanagan, and Davis and from McCabe and Ricciardelli, have shown that such cultural messages increase body image issues and disorders among boys.

Body dissatisfaction is commonly coupled with other problematic issues and disorders, such as body dysmorphic disorder, depression, low self-esteem, bigorexia, and anorexia and bulimia. The rate of occurrence of eating disorders (anorexia and bulimia), in males is still very low compared to that in females—of the estimated 8 million individuals diagnosed with eating disorders, 10% to 15% are males. However, specific prevalence rates among men are more difficult to determine and may be higher than reported because of the hidden nature of eating disorders and the false perception that eating disorders are found solely in females. Moreover, the societal stigma surrounding eating disorders is that of secrecy and shame; as a result, males with eating disorders often go to great lengths to hide their conditions.

According to the American Psychiatric Association, the primary ages for the onset of eating disorders for both males and females fall between 14 and 26 years, peaking at 14 to 18 years. Yet there is no compelling evidence that body image issues and dissatisfaction directly lead to disordered eating among adolescent boys.

Another disorder commonly associated with body image is *body dysmorphic disorder*, which is defined as a preoccupation or obsession with a "defect" in physical appearance, whether it is an actual imperfection or an imaginary one. "Defects" could range from a freckle on the neck or a scar from a childhood accident to a large nose or enlarged thighs. This preoccupation can be focused on any part of the body, independent of size, and typically leads to obsession with changing the "defect" by any means necessary. The individual's perception of the "defect" is distorted and commonly causes the individual to be consumed by thoughts of the problem. This usually leads to high levels of depression, low self-esteem, and fear of rejection, and coexists with obsessive-compulsive disorder and social phobia.

A third disorder associated with body image is *bigorexia*. Although not all physicians recognize this disorder, and no medical association has published relevant clinical guidelines, numerous psychiatrists and psychologists have observed and treated bigorexia since 1997. Bigorexia, also known as *muscle dysmorphia* and *reverse anorexia*, is a condition in which individuals are constantly worried that they are physically too small. The disorder is found primarily in the male bodybuilding community, and those suffering from bigorexia will go to any lengths to achieve bigger muscular bulk. They often spend hours in the gym lifting weights, pay obsessive attention to their diets, and are preoccupied with looking at themselves in the mirror. Although the causes are still unknown, physicians view bigorexia as a form of obsessive-compulsive disorder due to the pressure placed on men by media and society to conform to a certain physical ideal.

Overall, adolescent boys and young men are beginning to join females in their dissatisfaction with body image. Males are often distressed that they are not big enough, in marked contrast with females, who want to be smaller and thinner. Young men and young women alike experience low self-esteem when dealing with poor body image, and depression is common. Although body dissatisfaction issues such as dysmorphic disorder and bigorexia have not been directly linked to eating disorders, the connections are beginning to appear in therapy sessions as well as in clinical research. It is increasingly commonly believed that young boys are just as susceptible as young girls to pressure from media, peers, and family and are highly motivated to become what our society perceives as the "ideal" male.

BODY IMAGE IN CHILDREN

The concept of body image in children incorporates a number of factors, including awareness of one's appearance; perception of one's body shape in comparison to others; beliefs about appropriate or desirable weight, shape, and appearance; self-esteem, sensitivity, or embarrassment about one's weight and appearance; and judgments about other people concerning issues of weight, shape, and appearance. Children's body image is also linked to their actual weight and fitness as well as healthy eating and healthy activity behaviors. Distinct from eating disorders and obesity, body image is primarily perceptual (e.g., how accurately children view their bodies in comparison to others and to a healthy ideal) and emotional (e.g., feelings about their own weight, shape, and appearance).

Media messages may directly or indirectly undermine positive body image by showing unrealistic examples of body shapes and sizes as desirable or normal, promoting unhealthy eating behaviors, displacing activities that involve exercise or other esteem-building activities, and portraying people who are overweight as unintelligent, unpopular, and targets of ridicule. Girls receive more specific media messages about unrealistic ideals for weight and appearance than boys do, and girls are much more concerned about being too fat and about their overall appearance.

THE DEVELOPMENT OF BODY IMAGE IN CHILDHOOD

Although there is an enormous body of research and theory related to body image and eating disorders in adolescence and young adulthood (until recently, primarily focused on females), far less is known about the development of body image in childhood. By around the age of 2, most children have developed a self-concept, which gradually expands to include gender identity, racial/ethnic identity, specific physical characteristics (e.g., hair color, freckles), and clothing preferences. Somatic sensitivity (exaggerated dissatisfaction and embarrassment about overall appearance and specific body parts like ears or nose) does not usually show up until puberty; however, sensitivity about weight and body shape has become increasingly apparent at younger and younger ages. This decreasing age of onset for body dissatisfaction mirrors the increase in attention paid to issues of weight and appearance in the mass media and in popular culture in general.

The Measurement of Body Image in Children

Most of the commonly used psychometric scales and other measures of body image for adolescents and adults are not appropriate for use with children. The most widely accepted measures of body dissatisfaction in children involve scales of figures (shown as silhouettes, line drawings, or photographs digitally altered to hold facial features, hair, and skin tones constant). A set of seven to nine figures is shown, ranging from very underweight to very overweight; children select the image that most closely matches their own and the image that matches what they would

like to be. Assessment of perceptual distortions (i.e., discrepancy between a child's perception of his or her body shape and the actual shape) has been most effectively accomplished using video projection or video distortion techniques. Studies have shown very low incidence of perceptual distortions in body image among children, even for girls, until late childhood approaching puberty. Body dissatisfaction, however, is another story.

The Extent of Body Dissatisfaction Among Children

Until recently, researchers thought that children were relatively unaware of their bodies, and that social comparison and body dissatisfaction did not begin until puberty. Studies have now shown that children as young as 6 years old are already concerned about being overweight, and that by the third grade about half say they have been on a diet. The percentage of children who say they "like the way they look in pictures" declines dramatically across the elementary school years, and some studies have found that, among children ages 7 to 12, almost half the girls and one third of the boys want to be thinner. Although there seem to be few gender differences in overall appearance satisfaction and body esteem during early and middle childhood, dissatisfaction with weight and body shape is significantly higher for girls by second or third grade, and their idealized body size becomes increasingly thinner as they move through elementary into middle school. Findings from studies of body image in boys have been mixed; some show that boys experience similar declines in body dissatisfaction as they approach puberty (although they typically want to be bigger and more muscular rather than thinner), whereas other studies show that puberty may actually increase body satisfaction for boys.

Most of the research on body dissatisfaction has focused on Caucasian children. The few studies of body image in girls of color have sometimes shown higher body satisfaction among African American girls than among Caucasian or Latina girls, despite having a higher average BMI (body mass index) and earlier timing of puberty, presumably due to differences in cultural/ethnic ideals for body shapes and sizes. This may depend on the extent to which the child's community is made up of primarily Caucasian or African American individuals; children of color growing up in communities where nearly everyone is Caucasian may be more likely to adopt the thinness ideal of Caucasian culture.

Some research has shown that children's attitudes about weight and appearance extend to their judgments of others. One study found, for example, that even young children are less likely to select an overweight child to be their friend and more likely to identify a thin or normal-weight child as "good" than one who is overweight.

Many factors contribute to low self-esteem and body dissatisfaction, including comments from peers, parents, and other adults; parents' overt encouragement of their daughters to lose weight, for example, is associated with increased body dissatisfaction and dieting among girls.

MEDIA INFLUENCES ON CHILDREN'S BODY IMAGE

There has been very few studies linking media messages to body image per se in children, although there is quite a bit of research linking media use to obesity, dieting, and unhealthy eating behaviors. Until relatively recently, the relationship between media exposure and body dissatisfaction was largely inferred from content analyses of media portrayals and comments by adolescents and young adults about how insecure those portrayals made them feel.

Analyses of Media Content

Media messages about body image come primarily through visual and audio-visual formats, such as TV programs and commercials, movies, magazines, and video games. Of these, only television has been studied to any extent with respect to body image in children. A recent longitudinal study of body types shown in animated cartoons found an increase in presentations of characters who are underweight and a decrease in presentations of overweight characters, coupled with a clear tendency to show more positive messages about thinness and more negative messages about overweight. Content analyses of prime-time programs (frequently viewed by children) have shown an even more distorted "world" of body sizes, with underweight women appearing six times more often than they do in the real world. Overweight individuals appear only half as often as they do in reality, and they are usually shown to be unattractive, unsuccessful, and unpopular. Besides implicit messages about ideal body

size found in character portrayals, analyses of media content have also found frequent explicit messages about dieting, body shape, and the thin ideal. One study of prime-time programs found that 12% of the female characters said they were dieting, and it was common for female characters—even young teens—to make negative comments about their own appearance.

Barbie dolls are also representative of the unrealistic body ideal presented to children; if a Barbie doll were life size, she would have a 34-inch chest but only a 16-inch waist, 6-inch upper arms, and feet only 3-1/2 inches long. Similar distortions occur for boys' "action figures"; the musculature of these action figures has increased significantly since the 1960s, and if today's G.I. Joe dolls were life size, they would have upper arms measuring 26 inches around, 55-inch chests, and feet only 5 inches long.

Somewhat in contradiction to the unrealistically thin or muscular characters children see on television are the foods and eating behaviors found in TV commercials shown during children's shows. Many content analyses have demonstrated that the foods advertised to children are often high in sugar and fat, low in nutrients, and shown in much larger portions than are appropriate for a healthy serving. These high-calorie foods are then shown being eaten by happy, normal-weight (or even thin) children and families.

Media and Children's Attitudes About Weight and Appearance

Much of the research linking media portrayals with increased body dissatisfaction has been correlational or theoretical. One difficulty in studying this type of effect is that the influence of media on body image is almost certainly cumulative over time, making it difficult to demonstrate an effect using experimental methods or to measure actual media exposure over more than just a short period. Theoretical frameworks for studying these effects usually come from social comparison theory, social learning theories, internalization of the thin ideal, and investment in one's own appearance as key to self-evaluation.

Nonetheless, some empirical evidence is starting to accumulate that supports the influence of media messages on children's body dissatisfaction and attitudes about weight in general. One study of first-through-third-grade children found that TV viewing and interpersonal attraction to TV characters was predictive of boys' tendency to stereotype a fat female target, and predictive of increased eating disorder symptomatology for both boys and girls. A large longitudinal study of children ages 9 to 14 found that boys and girls who said they made a concerted effort to look like same-sex media celebrities were more likely later on to report concerns about weight than their peers; this was also predictive of purging for adolescent girls. Another recently published longitudinal study of children ages 8 to 12 found that the strongest predictors of engaging in strategies to lose weight (for both girls and boys) or increase muscles (for boys) were BMI (body mass index), influence of mothers, and media exposure.

INTERVENTIONS RELATED TO MEDIA ISSUES AND BODY IMAGE IN CHILDREN

Attempts to address these issues and influences with children generally fall into one of three categories. The first focuses on decreasing screen time or other media use, thereby decreasing exposure to media messages that undermine healthy eating and positive body image, and possibly increasing physical activity. Studies of this type of intervention have typically looked at effects on obesity rather than body image per se and have shown some success in slowing weight gain in children although not an increase in physical activity. The second type of intervention emphasizes boosting children's general self-esteem and self-expression through facilitated discussions as follow-up to viewing age-appropriate videos (such as those created by The Body Positive) or through teaching children to create their own video documentaries about their lives and coping with weight issues (such as the Video Intervention/Prevention Assessment initiative of Children's Hospital Boston).

The third type of intervention involves media literacy programs designed to help children critically analyze unrealistic and unhealthy media messages about body image and nutrition. Although such programs are increasingly popular in school and community-based settings, more empirical research must be done to document their effectiveness in developing children's resilience to unhealthy media messages about body image.

BODY IMAGE IN GIRLS AND YOUNG WOMEN

Mass media such as television and magazines are replete with messages about gender, attractiveness, ideal body shapes and sizes, and weight management. Girls and young women are exhorted to make the attainment of beauty their principal project in life. Since the middle of the 20th century, female beauty in the media has been defined chiefly in terms of a thin body. Consequently, negative body image and disordered eating rates among girls and young women appear to mirror media trends. As media-depicted body ideals have become more slender, the rates of disordered eating and body dissatisfaction among girls and young women have risen. Accordingly, media influences on weight and shape concerns in girls and young women have become the focus of much research.

TRENDS IN MEDIA DEPICTIONS OF THE IDEAL FEMALE BODY

The highest reported prevalence of anorexia nervosa and bulimia, both of which are eating disorders linked with the idealization of a thin body, occurred during the 1920s and again from the late 1970s to the present day. During these periods, the media-depicted body ideal was the thinnest in American history. The full-busted, full-hipped postwar television matron is outmoded, replaced by a slimmer, more independent, active female figurehead, exemplified by characters in media offerings ranging from fitness and fashion magazines to reality-based television shows popular with young female viewers, such as *The Swan* and *America's Next Top Model.*

Content analyses of female body shapes and sizes in popular magazines, entertainment television, and advertising reveal a number of trends. First, the ideal female body has become progressively thinner since the 1950s, reaching a low that has remained fairly consistent since the early 1990s. Second, the body sizes of female models and other media personalities tend to be markedly thinner than the body sizes of male models and media personalities. Moreover, media aimed specifically at young female audiences, such as fashion magazines, feature significantly more diet-related information and advertising than media aimed at male audiences. Third, thin female television characters are portrayed as more successful and more desirable than normal or heavy characters; research shows, for instance, that they are complimented more and insulted less by male characters than are fat female characters. Fourth, the discrepancy between the body sizes of women in the media and the body sizes of real American women has grown. One recent study showed that, as American women have become heavier, the magazine-depicted female body ideal has become slimmer; almost all the female models analyzed in this study were estimated to have body mass indices in the "anorexia risk" range. Thus, female audience members wishing to emulate the thin ideal must employ increasingly extreme measures to do so.

MEDIA EFFECTS ON BODY IMAGE

There is now a sizable collection of evidence that girls' and young women's images of their own bodies are influenced by the mass media's portrayal of the thin ideal. Experimental research on immediate, short-term effects suggests that exposure to ideal-body imagery, articles, advertisements, and entertainment portrayals results in increased estimates of the importance of sex appeal and beauty, decreased body satisfaction, overestimates of body size, increased body shame, decreased self-esteem, increased depression, and an increased drive for thinness. Research also shows that adolescents respond more to social information endorsing the thin body ideal than do adults, presumably because adolescents are highly sensitive about their changing body shapes.

Several theoretical processes have been identified in explanations of how media depictions of the thin ideal affect body image and disordered eating in girls and young women. The first of these is internalization of the slim body ideal. Several researchers have argued that internalization of this ideal—that is, adopting it as one's own personal standard—is a causal factor in the development of negative body image and disordered eating in adolescents and young women. Very recent research with girls in elementary school suggests, however, that media exposure can lead to extreme dieting even before it leads to thin-ideal internalization.

A second theoretical process explaining media's role in body image and disordered eating is social comparison with slim media personalities. Many studies have shown that exposure to ideal-body media such as fashion magazines activates a comparison process whereby girls and young women compare their bodies to the models and actors they see featured in the media. This often results in disappointment in one's own appearance, followed by the resolution to do whatever is necessary to resemble the target(s) of comparison. On the other hand, research has shown that exposure to normal or overweight models can temporarily raise girls' and young women's body esteem.

A third theoretical process explaining media's role in body image and disordered eating concerns emotional responses to ideal-body imagery and the role of emotion in eating behavior. Research on media exposure and self-discrepancies suggests that ideal-body media images can activate existing discrepancies between girls' perceptions of their bodies as they are and as they ideally would like them to be. The activation of such discrepancies gives rise to unpleasant emotions such as depression and anxiety, which then may be soothed through the strategic use and abuse of food.

INDIVIDUAL DIFFERENCES IN EFFECTS

Not all girls and young women are equally affected by exposure to thin-ideal media. Research has identified several moderators, or individual differences, that influence the strength of media effects on body image and disordered eating. The first such moderator is disordered eating itself. One study of the effect of exposure to magazine photographs of thin female models compared eating-disordered and nondisordered research participants. Nondisordered participants were not affected by the images, whereas disordered participants overestimated their own body size by an average of 25% after less than 10 minutes of exposure.

A second, related moderator is perceptions of personal physical attractiveness and self-esteem. One study measured 4th-, 8th-, and 12th-grade girls' responses to advertising and found that the tendency to compare the self to models in the advertisements increased with age and was stronger in girls with lower initial estimates of personal attractiveness and self-esteem. A related study showed that young women who were low "self-monitors" felt badly about their bodies after exposure to images of slender beauty. Low self-monitors are typically less responsive to situational demands and tend to be described by friends as introspective and anxious.

A third moderator is the context of exposure. Media exposure is not always a solo activity; it frequently takes place in the presence of an audience. Comments made by other audience members can influence the effect of media content on individual audience members. In one study, older female adolescents viewed slides of neutral images exclusively or slides of neutral images interspersed with slides of idealized slender beauty. Some of the participants viewed the slides alone, some viewed in the presence of two silent males, and some viewed in the presence of two males who made positive comments about some of the idealized slides. Surprisingly, when males commented, the effect of the idealized images was slightly *more positive* than the effect of the neutral images. This counterintuitive finding was replicated in additional research. It appears that the male commentary made participants conscious

of their reactions to the images. This conscious processing of appearance-related information may help young women activate a critical stance toward sociocultural messages about body shape and beauty.

Most of the research on media effects on body image involves older adolescent and young adult samples. Although the exact role of age as a moderator is still undetermined, there is some evidence that even young girls may be susceptible to the effects of ideal-body media. In one study, greater television viewing was associated with increased eating disorder symptomatology in a sample of 6-to-8-year-old girls. In another study, 9-to-12-year-old girls were assigned to view slides of adult models in advertisements from adult-targeted magazines, slides of young girls modeling in advertisements from child-targeted magazines, or slides of neutral scenes such as houses and boats. Girls exposed to peer but not adult models reported feeling heavier, less happy, less attractive, and less intelligent.

In spite of these findings, there is reason to believe that older adolescent girls are more vulnerable to ideal-body media effects than are younger adolescent girls. A study of Australian adolescent girls ages 12 to 13 and 15 to 16 showed that different characteristics made younger and older girls more susceptible to the effects of exposure to thin, attractive models. For younger girls, postexposure body dissatisfaction was highest for those with a greater body mass and a dispositional tendency to feel fat. For older girls, body dissatisfaction was highest for those with the same characteristics plus the more psychological characteristics of thin-ideal internalization and a tendency to compare their bodies to others' bodies. In developmental terms, growing psychological sophistication may combine with larger body size and a stable concern about being "fat" to render the impact of thin-ideal images greater for older adolescents.

A final notable moderator of ideal-body media effects is race and ethnicity. African American and Latina girls tend to embrace more curvaceous body ideals and consequently display more resistance than white girls to the ultra-thin body ideal conveyed through mass media that target primarily white audiences. Because most conspicuously thin models and characters in American media are white, resistance to this ideal may stem from less social comparison overall because white media personalities are not perceived by girls of color as personally relevant. As more and more models and media personalities of color conform to the ultra-thin body ideal, however, this pattern may change.

PREVENTION OF EFFECTS

Most efforts at prevention have concentrated on teaching media literacy to girls and young women. Media literacy refers to the process of learning about and critically analyzing media institutions, conventions, motivations, formal features, and message structures and meanings. The goal of media literacy is selective, informed, and empowered media consumership; cynicism and blanket condemnation of pleasurable media use are generally viewed as unrealistic and even counterproductive given that girls must live in a media-saturated society.

Research on body-focused media literacy suggests that informational curricula can be effective. One such curriculum began by showing adolescent girls portions of videos featuring scholarly critiques of the thin female media ideal, followed by footage depicting computer retouching of supermodel Cindy Crawford's image for a magazine layout. The girls then practiced critical analyses of media popular with their peers and discussed the implications of the inevitable discrepancy between real girls' bodies and the "perfect" images in the media. Compared to girls who had not participated, girls exposed to this curriculum subsequently reported better body image and less social comparison with media images. The effects of the curriculum were limited, however; there was no reduction in internalization of the slender beauty ideal or in disordered eating.

Longer-term media literacy programs appear to be more useful for effecting durable attitude and behavior changes. One curriculum involving six 90-minute lessons encouraged girls to be activists by helping peers and by working to change mass media to establish healthier norms. The girls in the program critically evaluated advertisements and then wrote letters to businesses to advocate healthier images. These letters were posted on the website of the National Eating Disorders Association to promote activism and advocacy by other girls. Three months after the conclusion of the curriculum, participants were less likely to read teen fashion magazines promoting the thin body ideal. They also reported reduced thin-ideal internalization and increased faith in their ability to be activists and to influence weight-related social norms. Still, the curriculum had no effect on dieting and no sustained effect on body size acceptance.

Given the ubiquity of the slender beauty ideal in American mass media, it is not surprising that even long-term, intensive media literacy programs can only go so far in protecting girls and young women from the effects of ideal-body media. Replacement of these media with healthier options is a different prevention strategy that has been tested in recent research. In a study of women's sports media, white adolescent girls reported less self-objectification following exposure to fuller-bodied female athletes than after exposure to lean female athletes or male athletes. African-American girls, however, reported *more* self-objectification after exposure to fuller-bodied female athletes, perhaps because the shape of these athletes' bodies was a closer match to their pre-existing ideals. This research suggests that, as long as female models, athletes, television characters, and other media personalities are portrayed in a manner that objectifies them by drawing attention to their appearance, exposure to media featuring them may be harmful to girls. At present, it appears that the best prevention may be for parents, teachers, mentors, and other influential adults to encourage the girls in their lives to avoid appearance-relevant media altogether and instead spend their time with media that focus on those aspects of human life—such as hobbies, careers, and relationships—that transcend appearance.

BOOKS FOR ADOLESCENTS

Reflecting aspects of our everyday lives, books mirror the personal experiences, ideologies, and moral standards of people residing within a particular culture, time period, and social environment. Books written specifically for adolescents afford them an understanding of their changing bodies and social environments and provide characters whose lives parallel their own. Commonly, books for adolescents are referred to as *young adult (YA) literature, adolescent literature,* or *teen literature.* This body of literature, generally written for readers between the ages of 12 and 18, has evolved from a smattering of prudent, low-quality, formulaic books to an extensive collection of radical, high-quality, original novels written by established authors from various cultural and generational backgrounds. In addition, YA literature represents an array of genres that changes with respect to

the new trends in American publishing and book merchandising. Specialized awards recognizing literary merit and adolescent appeal have been created for YA literature by educational organizations such as the American Library Association and the International Reading Association.

CHARACTERISTICS OF YA LITERATURE

YA books guide adolescents through the process of learning the proper social codes necessary to function within a particular culture. Through the use of adolescent characters, YA books present familiar situations encountered by adolescents in their daily lives while also providing problem-solving strategies that help adolescents deal with their personal difficulties. Likewise, the various genres of YA books assist adolescents in their social and moral development. These genres include nonfiction as well as the following fiction categories: realistic, romance, adventure and survival, mystery and supernatural, historical, fantasy and science fiction, and sports.

High-quality YA literature that successfully attends to the angst experienced by adolescents has several recognizable characteristics. First, authors of YA literature must write from an adolescent viewpoint to ensure that readers will identify with the characters. Second, adolescent characters should be free from parental restrictions, allowing them to take credit for their accomplishments. YA books should also be written about a variety of subjects and have fast-paced narratives that complement adolescents' multimedia and multitask lives. Likewise, YA books need to include stories about characters from diverse ethnic and cultural groups, including characters of varied socioeconomic status, race, ability, gender, age, religion, and sexual orientation. Moreover, books for adolescents must be generally optimistic, with adolescent characters making worthy and believable accomplishments that the readers will respect. Finally, YA books should deal with emotions that are important to adolescents—achieving emotional independence from parents, preparing for sex, accepting physical changes in one's body, and developing personal morals and ideology.

BRIEF HISTORY OF YA LITERATURE

Prior to the 1950s, YA literature was characterized by gender-specific series; adventure and Western books were published for adolescent boys, and books with virtuous female characters were created for adolescent girls. From the 1950s to the mid-1960s, series books were replaced by sanitized, formulaic books about teen romance and school life. In the late 1960s and early 1970s, YA literature experienced a radical transformation with the publication of S. E. Hinton's *The Outsiders* (1967), Paul Zindel's *The Pigman* (1968), Judy Blume's *Are You There, God? It's Me, Margaret* (1970) and Robert Cormier's *The Chocolate War* (1974). While describing in detail the emotions and angst of their characters, all four of these ground-breaking novels related the real problems and experiences that adolescents face daily. As a result, subsequent realistic YA novels were published, leading to the era of the problem novel from the 1970s to the early 1990s. The prominent theme of these novels centered on the coming-of-age experience of the adolescent characters, a process that requires characters to accept or reject the responsibilities and social codes necessary for functioning within a society. Coming-of-age experiences include such issues as depression, eating disorders, pregnancy, puberty, sexuality, peer pressure, school problems, family relations, drug and alcohol abuse, religion, and ethnic pride. Often, problem novels written between the 1970s and early 1990s addressed a social issue but failed to provide a positive outcome.

From the mid-1990s to the present, authors of YA literature have sought to address the realistic problems faced by adolescents using alternative formats (graphic novels or journal-style narratives) and creative approaches (varying points of view and unique futuristic or historical settings). Current YA books are positively tackling taboo topics such as incest and transgender with clarity and sensitivity while employing harsh language and experiences to present the reality of adolescent life. Acceptance of the alternative or being the outsider is a recurring theme in YA novels. Recent examples of these books are Stephen Chbosky's *The Perks of Being a Wallflower* (1999), Laurie Halse Anderson's *Speak* (1999), Julie Anne Peters's *Luna* (2004), An Na's *A Step from Heaven* (2001), G. L. Going's *Fat Kid Rules the World* (2003), and Craig Thompson's graphic novel *Blankets* (2003).

CURRENT TRENDS IN YA LITERATURE

YA literature has seen various trends influencing the books available to adolescents. The recent trends, according to Michael Cart's monthly *Booklist* column "Carte Blanche," include the following:

The emergence of fantasy as one of the most popular adolescent literature genres

An increase in adult authors–such as Carl Hiaasen, Juliva Alvarez, Joyce Carol Oates, and Michael Chabon–writing for adolescents

The development of crossover fiction novels, such as Francesca Lia Block's *Weetzie Bat* books, that appeal to multiple generations

An influx of "commercial" fiction books, such as Ziegesar's *Gossip Girls* and Cabot's *Princess Diaries* series, which are low in literary quality but high in adolescent appeal

An explosion of graphic novels including Japanese manga

The invasion of international book series like J. K. Rowling's *Harry Potter,* Louise Rennison's *Confessions of Georgia Nicholson,* and Eoin Colfer's *Artemis Fowl;* and

The publication of more sexually liberated books such as David Levithan's *Boy Meets Boy* and Paul Ruditis' *Rainbow Party*

AWARDS FOR YA LITERATURE

Numerous awards are given to the author's of YA literature. Each year, the American Library Association presents the following awards and honors to YA literature: the Printz Award, Best Books for Young Adults, Quick Picks for Reluctant Young Adult Readers, the Alex Awards, the Margaret A. Edwards Award, Popular Paperbacks for Young Adults, and Teens' Top Ten. Likewise, the International Reading Association awards the Young Adults' Choices. For more information on these awards, consult www.ala.org/yalsa/booklists and http://www.reading.org/resources/tools/choices_young_adults.html.

BOOKS FOR CHILDREN

The literary genre *children's books* or *children's literature* generally refers to the broad range of texts published for young audiences from birth to 12 years. From board books to fictionalized novels, the contents of these books are influenced by myriad factors, including the current knowledge of child developmental learning, personal ideologies of the authors and illustrators, social and political cultures surrounding the books' publications, and economic realities within the children's publishing industry. Likewise, children's books reflect society's views regarding moral standards and lifestyle choices. Trends in children's publishing are dictated by these views as well as the corporate philosophy regarding book sales. As a result, issues concerning children's book publication, such as censorship and cultural authenticity, are often raised by literary critics and concerned members of society. In an effort to increase the quality of children's books and to encourage multiculturalism in children's publishing, children's book awards are given by numerous educational organizations such as the American Library Association and the National Council of Teachers of English. These awards encourage publishers to meet quality standards set forth by the award committees, resulting in books of higher literary value that avoid cultural stereotypes and promote acceptance of all cultures.

CHARACTERISTICS AND GENRES OF CHILDREN'S BOOKS

Various researchers and educators have generated lists of criteria for "good children's literature." Essentially, they all agree that children need books that are accurate and insightful, aesthetically pleasing, and free of stereotypes or negative cultural representations. In addition, children's books should broaden the reader's

understanding and awareness of a topic and should be developmentally appropriate for the intended age level. Books possessing these qualities help children understand themselves, others, and the changing world around them.

Choosing the right books for the right readers enriches children's lives and imaginations as they encounter new worlds, new characters, and new situations through the various genres of children's books. Barbara Peterson (2001) describes the textual characteristics of "good" children's books, emphasizing the literary genres most suitable for each stage in a child's development. Genres of children's books include traditional literature (folktales, myths, legends, and fables from around the world), picture books (board books, concept books, beginning reader's books, picture storybooks, and wordless books), poetry (nursery rhymes, songs, and various forms of poems), realistic fiction (books dealing with mystery, humor, sports, school, families, etc.), historical fiction (books set in past times and places), modern fantasy and science fiction (books with talking animals, imaginary creatures, and invented settings), biographies and personal memoirs (books about the lives of famous people and ordinary people), and informational and nonfiction books (factual books on a multitude of topics, from nature and animals to sports and history). *Children's Books in Children's Hands,* by Charles Temple, Miriam Martinez, and Junko Yokota, provides a comprehensive description of the various children's book genres.

CHILDREN AND BOOKS: INTERACTING AND RESPONDING

Interactions With Books

Children need daily opportunities to interact and respond to texts if they are to realize the full potential of books. Jim Trelease enumerates the many prosocial and developmental (physical, intellectual, and emotional) benefits of reading aloud to children from books, noting that the most successful, well-adjusted, and intelligent adults grew up in families where reading is valued and read-alouds are common. Esmé Raji Codell offers comparable statistics and provides an extensive list of recommended books, arranged by subject and age level, to assist parents in selecting age-appropriate books to read to their children. She describes additional activities that encourage children to interact with books, such as reader's theatre dramatizations, puppetry, storytelling, literature-based cooking, book-themed parties, story writing, and poetry readings.

Responses to Books

Considerable research, particularly in the area of literary criticism, has been conducted on children's responses to books. Scholars are undecided as to which aspect of the reading experience influences a child's understanding of a book's message. Lawrence Sipe profiles the various theories of children's responses to literature, examining the influence of the author, text (book), reader (child), and context (reading environment) on the meaning that a child constructs from a book. Some theories of reader response indicate that the author's personal ideologies, written into the text of the book, influence the message that a child comprehends. On the other hand, textual theories maintain that the text contains gaps that must be filled in by the reader's previous life experiences and intertextual encounters before the reader can understand the message of a book. These theories also assert that illustrations, laden with the concealed ideologies of society, hold meaning for the reader and supplement the meaning in the text. Reader-focused theories suggest that the personal ideologies, ethnicity, culture, gender, sexuality, and socioeconomic level of the readers inform the meaning they construct from books. Finally, contextual theories of reader response explain that the reading environment surrounding a child's interaction with a book influences the meaning of the text by imposing the social, political, and cultural demands of the environment on the reader. Regardless of which theory of reader response is adopted, researchers concur that a child's understanding of a book is socially constructed, providing a partial view of the world's past, present, and future.

CURRENT TRENDS AND ISSUES IN CHILDREN'S BOOK PUBLISHING

Industry Trends

As a result of corporate mergers, children's book publishing has recently experienced numerous changes in the types of books available to consumers. Over the past 10 to 15 years, the big media companies have purchased the children's publishing houses, incorporating the houses into their media conglomerate of news and

entertainment businesses. The significance of these takeovers is exhibited in the quality and types of children's books being published. Considerable emphasis on the licensing and branding of book and television characters has resulted in a plethora of licensed-character products. Children's television programs such as *Dora the Explorer, Blue's Clues, Scooby Doo,* and *SpongeBob SquarePants* have all expanded into the realm of children's books with a multitude of coloring books, board books, picture books, and novels exhibiting licensed characters from the shows. Likewise, children's book characters such as Curious George, Shrek, Harry Potter, and Madeline have appeared on the silver screen, apparel, and snack foods. Children's book publishers have also made agreements with toy companies to create books with licensed toy images such as *Barbie, My Little Pony,* and *Transformers,* or to create toys with licensed character images such as those from the lucrative *American Girl* series. Similarly, greeting card companies have contracts with children's publishers for books with licensed characters such as *Care Bears* and *Strawberry Shortcake.*

A successful example of corporate mergers and licensing in children's book publishing is the enduring *Harry Potter* craze. Published in Britain in 1997 and in the United States in 1998, *Harry Potter and the Sorcerer's Stone* has evolved from a single children's fantasy book to a globally profitable business venture that includes multiple movies and licensed products ranging from notepads and barware to clothing and video games. Both children and adults are passionate for Potter, creating websites, chat rooms, and blogs dedicated to the British book character.

Directly resulting from this phenomenon is the trend in children's publishing for the increased production of fantasy book series. Because of the huge success of the *Harry Potter* series, children's interest in the fantasy genre has dramatically increased as they seek more books like the *Harry Potter* series. Children's publishing houses have responded by introducing over 400 new fantasy-themed books each year.

Another trend in children's book publishing, a result of the big media mergers, is the popularity of celebrity authors. Recently, various actors and music artists have published children's picture books as original stories and book-length song adaptations. Examples of these books include works by Madonna, Dolly Parton, Jamie Lee Curtis, Jay Leno, and Vince Gill.

Two additional trends in the children's book industry are the increased publication of bilingual picture books and the introduction of beginning-level novels with Spanish phrases and code switching. With the growth of the Latina/o population in the United States, the demand for bilingual and/or Spanish language picture books has dramatically increased. Educators and parents seek children's books that will help Latina/o children learn English and help American children learn Spanish. Also, in an effort to meet this demand for bilingual literature, publishers have launched beginning-level novels that combine Spanish words and phrases within the text and storyline. Code switching—the use of both Spanish and English words without explanation of the Spanish words—has become quite common in children's books in an effort to make them appear more multicultural. An example of this type of beginning-level novel is the *Friends and Amigos* series written by Patricia Reilly Giff. It should be noted that, although the publication of books with Spanish words or phrases has increased, the production of books about the Latina/o population has remained the same, with little emphasis on the diversity of the Latina/o culture.

Quality and Diversity in Children's Book Publishing

The merger of children's publishing houses with media conglomerates has created various issues for the children's publishing industry. Many children's literature professionals and educators have accused the big media publishing houses of focusing on product sales rather than literary quality. Instead of providing high-quality books that will support children's developmental growth and learning, the book publishers are charged with publishing low-quality books, such as celebrity-authored or licensed-character books, that are wholly driven by sales.

Children's literature professionals and educators also maintain that publishing houses fail to produce authentic multicultural literature, because such books do not equate with high revenue. As a result, minority children, who need to see themselves represented in the literature they read, encounter stereotypical presentations (or no representations) of their cultures in their reading selections. Many other issues surrounding the accurate representation of culture, gender, race, sexuality, ability, and religious affiliation are discussed by Dana Fox and Kathy Short in their book *Stories Matter.*

Censorship

Censorship is an additional issue within children's book publishing. When a book's message presents a view of society that is unfavorable or that advocates for anti-mainstream values, it often falls victim to critics who try to censor its contents. Censorship can take mild forms, such as requests that a book be removed from a particular library section or from the holdings of a library. Censorship can also result in extreme measures, such as burning or defacing of books whose messages critics find offensive or potentially harmful to society. Children's books have been censored for various reasons: use of offensive language, particular treatment of a topic, addressing inappropriate or "adult" topics (e.g., sex, drug abuse, violence), inappropriate illustrations, and so on. Recently censored children's books include J. K. Rowling's *Harry Potter* series, because the books deal with witchcraft, and Linda De Haan and Stern Nijland's picture book *King and King,* because it proposes acceptance of gay marriage.

AWARDS FOR CHILDREN'S LITERATURE

To encourage high literary standards and the publication of books about various minority groups, numerous awards for children's books are presented. The two most distinguished American awards for children's literature, the Newbery and the Caldecott, are awarded annually by the American Library Association (ALA). The Newbery Medal, originally awarded in 1922 and the first award ever presented to a children's book, honors the most original, creatively written American children's book published the previous year. Likewise, the Caldecott Medal, originally presented in 1938, honors the most distinguished American children's picture book published the previous year. Honor books, or runner-ups for each award, are also recognized yearly. Other children's book awards presented by ALA include the Mildred L. Batchelder Award for translated works, the Pura Belpré Award for Latino/Latina writers and illustrators, the Coretta Scott King Award for African American writers and illustrators, the Laura Ingalls Wilder Medal for authors whose works have made a major contribution to children's literature, the Robert F. Siebert Informational Book Medal for the most distinguished informational children's book published the preceding year, and the Theodor Seuss Geisel Award for the most distinguished beginner-level book published the previous year.

Additional awards for children's literature are administered by numerous educational organizations and include the Américas Award for Children's and Young Adult Literature, presented by the national Consortium of Latin American Studies Programs; the Hans Christian Andersen Award, presented by the International Board on Books for Young People; the Children's Book Award, presented by the International Reading Association; the Ezra Jack Keats New Writer Award, presented by the Early Childhood Resources and Information Center of the New York Public Library; the NCTE Award for Excellence in Poetry for Children, presented by the National Council of Teachers of English; the Orbis Pictus Award for Outstanding Nonfiction for Children, presented by the National Council of Teachers of English; the Scott O'Dell Historical Fiction Award, presented by the Advisory Committee of the *Bulletin of the Center for Children's Books;* the Jane Addams Book Award, presented by the Jane Addams Peace Association; and the Tomás Rivera Mexican American Children's Book Award, presented by Texas State University–San Marcos. The British Library Association administers two other highly significant children's book awards: the Carnegie Medal (the equivalent of the Newbery Medal) and the Kate Greenaway Medal (the equivalent of the Caldecott Medal).

BOY BANDS

As manifested in the late 1980s and throughout the 1990s, the boy band formula is to combine somewhere between three and six (typically four or five) young, singing and dancing males; to have each represent a distinct personality type; to carefully choreograph their (individual and band) images as closely as their dance steps; and to mass-market them to an audience consisting mostly of preteen and teenage girls. Such bands often play a unique role in the lives of preteen and young teen girls, serving as a bridge between childhood and adolescence. The "boys" in the band (although often significantly older than their tween and young teen fans) may provide "safe" crushes for girls to fantasize about.

New Kids on the Block, New Edition, the Backstreet Boys, *NSYNC, 98 Degrees, O-Town, Menudo, the Monkees, and the Beatles rank among the most famous and successful boy bands of all time. Although they don't fit the standard formula of having been manufactured by an impresario such as Pearlman, the Beatles are considered by many to be the precursor to the modern boy band, notably because of their frenzied reception by teenage girls enamored not only of their music but also of their hairstyles, looks, and unique personalities.

Although the evolution of boy bands can be traced back to the Monkees (and, some would even say, to the doo-wop groups of the 1950s), the modern boy band formula was pioneered in the 1980s by Boston-based music producer Maurice Starr, who at one point managed and discovered (although he did not create) the highly successful New Edition in the early part of that decade. MTV.com calls New Edition the forefathers of the boy bands of the 1990s. The group, all teenagers originally from the predominantly African American Roxbury section of Boston when they hit it big, soon fired Starr when they left his small Streetwise label to sign with MCA. After splitting initially in the early 1990s, the members of New Edition, including Bobby Brown, Johnny Gill, Ralph Tresvant, and the group Bel Biv DeVoe, went on to highly successful projects, while Starr went on to create New Kids on the Block.

Attempting to recreate his New Edition success, Starr created a new group, this time with white teens. The new group, New Kids on the Block, like their boy band successors, appropriated and adapted African American performance, vocal, and dance styles. Moreover, the New Kids' success was a function of MTV exposure, which provided a visual venue by which to market musical acts who might not have been able to get by on questionable musical talent alone. The New Kids sold millions of albums in the late 1980s and very early 1990s. While their fame was short lived, they left behind the formula for boy bands of the 1990s. The late 1990s were the heyday of boy bands. They dominated the charts and MTV airplay and received extensive media coverage.

Seeing the success of New Kids and recognizing the money to be made by managing such an act, Florida-based entrepreneur Louis Pearlman, arguably the best-known boy band manager, held open auditions in 1993 for the group that was to become the Backstreet Boys. After the group had toured small venues such as high schools and Sea World for 2 years, Pearlman sent them to Europe, where they became a huge hit, with Top Ten singles in almost every European country. Returning to the United States in 1997 with the re-release of their debut album *Backstreet Boys*, the band hit it big. The album, which came in at number three for the year, went on to sell 27 million copies and spawned five hit singles. Released in the summer of 1999, the Backstreet Boys' second U.S. album, *Millennium*, debuted at number one, selling over a million copies in its first week alone.

While still working with the Backstreet Boys, Pearlman went on to create rival boy band *NSYNC in 1996, which became almost as successful as its predecessor. Not stopping there, Pearlman created other boy bands, including O-Town, a band whose genesis was documented in an ABC reality series *Making the Band*—a successful series of programs that celebrated the prefabricated nature of such boy bands.

Most boy bands end up fizzling out or splitting up, often in a legal wrangle with their creators or managers. But they were never designed to be more than flashes in the pan, as their fickle fan base moves on to the next big thing or simply outgrows the boy band phase.

Although boy bands have become a cornerstone of girl culture, men in general and male music critics alike have criticized boy bands. Some scholars suggest that the entrenchment of the bands in girl culture has generated this backlash. For example, Gayle Wald locates this animosity within a broader, long-standing cultural devaluation of all things feminine, notably music enjoyed by teenage girls (derisively labeled "teenyboppers"). It is, she says, part and parcel of "a misogynist contempt for girls and girls' pleasure" (Wald, para 31). In this case, she argues, it is the "girlish masculinity" enacted by these bands that accounts both for their popularity with preteen girls and for the derision heaped on them by males in general and male music critics in particular.

BRANDING

Branding is defined as the use of a name, term, symbol, or design to identify an organization, product, or service. The brand name Nike, for example, refers to the goddess of victory, while the swoosh logo is meant to convey speed and movement. Now the world's largest sports and fitness company, Nike was initially known for producing shoes for track events. A key competitor, Reebok, is named for an African gazelle, a species known to be powerful jumpers, very fast and graceful. The Adidas brand name is derived from the first three letters of the first name and surname of Adi Dassler, who was the company's founder. Several corporate brand names reflect the founder(s) and heritage of the company (e.g., The Walt Disney Company and Kellogg). Studies reveal that children at early ages can readily recognize and identify product logos, although some research indicates that brand recognition increases with age.

BRAND NAMES

Effective brand names are often short and simple; easy to spell, read, and pronounce; pleasant-sounding, distinctive, and memorable (easy to recognize and remember); timely (unlikely to become out of date); legally available for use (not in use by another firm); and applicable to multinational purposes. World Wrestling Entertainment (WWE), for example, was formerly known as World Wrestling Federation Entertainment and utilized WWF as an acronym, but the media and sports entertainment company was prompted to consider a new name and logo after the World Wildlife Fund prevailed in a United Kingdom court case in which was alleged the possibility of confusion in the marketplace with both organizations using the acronym WWF. As companies enter international markets, it is important to be mindful of how particular brand names translate into other languages. Gerber, the world's best known manufacturer of baby

Many popular novelty products feature beer themes and brand logos. Budweiser appears especially frequently on such merchandise, which ranges from the six-pack bank shown here to toy trucks, basketballs, apparel, and kitchen accessories.

food, is a corporate name that reflects the company's founders; however, a significant consideration when introducing their products to French-speaking nations was that the French word *gerber* means "to vomit."

A good brand name also commonly suggests something about the product's benefits, is adaptable to packaging and labeling needs, and will be appropriate for new products that may be added as line extensions at a later date. Many brand names are fairly descriptive about the product being identified (e.g., OFF! insect repellent and Toys 'R' Us). Although Dunkin' Donuts is a highly memorable brand name, the corporate identifier potentially could prove limiting if the company later became better known for other food products.

LOGOS

The logo is the visual element used to define a firm or brand. Common objectives in the design of logos are (1) a highly memorable style, (2) identification of the company's product, and (3) boldness, simplicity, and ease of reading. For example, the logo that identifies Blockbuster video stores is uniquely shaped, resembling a movie ticket stub, and the capitalized lettering and vivid colors contribute to the store signs' high visibility. Ideally, logos are durable and have a timeless quality. The Columbia Broadcasting System (CBS) television network's "eye" motif, in use since 1951, exemplifies both the viewer's eye and the lens of a camera. The peacock symbol of the National Broadcasting Company (NBC) reflects the television network's heritage as the first all-color broadcaster in the United States. The American Broadcasting Company (ABC) logo now in use was designed by Paul Rand in 1962 and depicts the lowercase letters *a, b,* and *c* in three circles of the same size framed by a larger circle.

TAGLINES AND TYPOGRAPHY

A branding strategy is also collectively constructed through taglines, typography, characters, and primary and secondary colors. Taglines or slogans are commonly developed with the objective of finding a phrase that is understandable, is memorable, and links benefits or positive images with a brand. A tagline is meant to succinctly communicate the company's message about the essence of a brand. Enduring advertising taglines include "Just do it" (Nike) and "Breakfast of champions" (Wheaties). The use of various typefaces and fonts plays a role in identifying and differentiating brands. Calligraphic writing of a brand name will likely suggest an exclusive product or prestige-oriented brand because calligraphy is commonly reserved for special occasions and events, most notably in wedding invitations and announcements. The "striped" lettering and typeface of IBM's logo conveys continuity, which is fitting for a computer systems company. In 2005, AT&T introduced a new corporate logo in lowercase type to express a more welcoming and accessible image. Highly recognized characters or icons include the Marlboro Man, Ronald McDonald, the Pillsbury Doughboy, and Tony the Tiger. Finally, color can play an important role in distinguishing brands and communicating both imagery and product characteristics. Generally, red evokes strong feelings related to passion, danger, anger, love, sex, strength, and power, whereas gold is the conventional color of money and brings to mind feelings of security, wealth, abundance, and preeminence. Blue is frequently associated with calmness, coolness, introspection, wisdom, and solitude, whereas green suggests nature, renewal, new beginnings, healing, health, and harmony.

BRANDING EFFECTIVENESS

Several principles are considered cornerstones of the effective communication of brand identity or image. Effective media messages are typically repetitive, continuous, and consistent. A message that is highly repetitious over time and across multiple media usually requires a considerable promotion budget. Companies often spend a large proportion of their promotion funds on one or two leading brands (i.e., those that have demonstrated popularity). Although the communicated brand essence may remain the same to ensure continuity and consistency, different symbols may be employed over time and across cultures to remain relevant, contemporary, and appealing to an ever-changing audience.

CHILDREN AND BRAND RECOGNITION

Several scholars and journalists (e.g., see Juliet Schor's *Born to Buy*, Susan Linn's *Consuming Kids: The Hostile Takeover of Childhood*, and Alissa Quart's *Branded: The Buying and Selling of Teenagers*) have been highly critical of the commercialization of childhood and the apparent identification of increasingly younger age groups as target markets by corporations

and advertisers. Paul Fischer and colleagues assessed recognition levels of 22 brand logos by having preschool children aged 3 to 6 match logo cards to one of 12 products pictured on a game board. They found that the overall recognition rate of the Disney Channel and McDonald's logos were 92% and 82%, respectively, and that 91% of the 6-year-old children in their sample matched the Old Joe Camel character with a cigarette. Logo recognition was highly associated with age for each of the assessed product categories (i.e., recognition rates were higher among the older participants).

BRITISH BROADCASTING CORPORATION (BBC)

Since its origins in 1922, the British Broadcasting Corporation (BBC) has grown to include interactive TV channels, radio networks, more than 50 local TV and radio services, and a website. The BBC has made a point of providing a complete range of programming for children throughout its history.

The British Broadcasting Company, as the BBC was originally called, started in 1922, when the United Kingdom's six major radio manufacturers set out to exploit the new invention. Broadcasters were not allowed to advertise but were financed by an annual license fee of half a pound, payable by anyone owning a receiver and supplemented by royalties on radio sales. The first broadcast came from London on November 14, 1922. A month later, John Reith (much later, Lord Reith) became general manager. After supporting the government in its coverage of the 1926 general strike, the company was dissolved, and the British Broadcasting Corporation was formed with a royal charter.

Radio grew during the 1930s, with particular attention to national and sporting events; the BBC also became a major patron of the arts, commissioning music and drama. In 1932, the HQ Broadcasting House in London opened as the center for radio production, as did the Empire (Radio) Service, the precursor of the World Service. Television arrived on November 2, 1936, but was suspended at the outbreak of war in 1939. Newsreader Bruce Belfrage was on air when 500 pounds of explosives hit Broadcasting House in October 1940. He paused as he heard the bomb go off during his nine o'clock bulletin but continued as normal, as he was not allowed to react on the air for security reasons. Seven people were killed.

Peacetime saw the resumption of one television channel; radio provided two national stations and, from 1946, the Third Programme, which featured music, drama and the arts. The Empire Service continued as the External Service, now receiving a grant-in-aid from the government, a situation that continues today with the World Service. In 1955, television ownership was boosted by the broadcasting of the Queen's coronation.

Competition emerged in 1955 in the form of the commercial, non-BBC Independent Television channel (ITV). The Television Centre in west London opened in 1960, and a second television channel, BBC Two, was launched in 1964. By 1967, radio expanded to provide four stations, and color was added to BBC Two.

In the 1970s, the BBC began broadcasting Open University programs. Teletext arrived in 1974, with early Ceefax transmissions (subtitling for the deaf)

coming 5 years later. Facing increasing competition from commercial radio and Channel 4 television, the BBC expanded with new channels. World Service radio was complemented by a BBC World television service, and satellite channel UK Gold helped it exploit the BBC's valuable archives.

By 2005, the BBC provided 8 interactive TV channels, 10 radio networks, more than 50 local TV and radio services, and the BBC website at www.bbc.co.uk. The BBC also runs social action, education, and minority language programs and maintains several orchestras. In 2004–2005, 95.6% of the UK population used the BBC at least once per month, and the BBC's royal charter was expected to be renewed in recognizably similar form to in 2006, with the BBC still financed by a license payable by each household.

Current children's programming on the BBC includes a daily magazine program called *Blue Peter,* which covers a wide range of entertaining and challenging activities (http://www.bbc.co.uk/cbbc/bluepeter). *Newsround* (http://news.bbc.co.uk/cbbcnews) is a daily newscast that deals with domestic and world events, reported concisely and without condescension for an audience aged 8 to 14. These and a host of other materials are also carried on the Internet and on two channels available via cable, namely CBeebies for the younger ages (www.bbc.co.uk/cbeebies) and CBBC for children and young teenagers.

For the quality and diversity of its output, its veracity as a news service, and its iconic role as emblematic of the nation, the BBC can be described as the world's most esteemed broadcaster.

C

CARTOONS, EDUCATIONAL

Although the possibility that television may negatively impact its audiences is the subject of frequent discussion, often without the support of research, less frequently entertained is the idea that television viewing may also have positive affects. The general assumption often seems to be that children are passive and do not expend any mental effort while watching television, but the literature in this area does not support this reasoning. In fact, there is no inherent reason why television viewing cannot foster prosocial and educational skills in its viewers. A number of excellent children's programs and cartoons have been highly successful in teaching young audiences, including *Arthur, Barney & Friends, Sesame Street, Blue's Clues, Dora the Explorer,* and *Mister Rogers' Neighborhood.* Successes of this nature are demonstrated in a 1979 study conducted by Dorothy and Jerome Singer, who found that television viewing among preschool children was positively related to aggressive behaviors except in those children who viewed educational programs such as *Sesame Street, Zoom,* and *Mister Rogers' Neighborhood.* Viewing of these educational shows was positively correlated with cooperative behaviors and other prosocial interactions between the children (such as friendliness and altruism).

Of the educational programs designed for children, the majority have been created for the preschool audience. *Sesame Street* has been the subject of the largest amount of research by scholars, but other programs, such as *Mister Rogers' Neighborhood* and more recently *Blue's Clues* and *Dora the Explorer,* have also been discussed in terms of their effectiveness in teaching children learning and reading-readiness skills as well as ways to positively interact with peers.

SESAME STREET

Numerous books and articles have been written on *Sesame Street* since its launch during the 1969–1970 season. Since then, the curriculum created for *Sesame Street* has relied on academic research and child development experts as program consultants in order to reach its educational goals. *Sesame Street* was developed for preschool audiences at a time when America was focused on fighting the War on Poverty, and the Children's Television Workshop creators were interested in gaining the attention of poor and minority child audiences who had less access to educational experiences and who stood to benefit most from viewing stimulating programming. Specific educational goals were set to promote cognitive development, and production techniques were designed to maximize children's visual attention. Different ways are used to retain children's attention during educational programs, including *Sesame Street*. Some of these are incorporating humor, cutting between live action and animated segments, and using children's and women's voices during the programming. For example, during an episode of *Sesame Street,* learning to count might be turned into a song and repetition employed to develop memory skills. These types of features retain the attention of the preschool audience and reinforce the skills taught during each episode.

Although *Sesame Street* was evaluated when it was launched to the public, some years went by without further assessment of the program and its impact on the preschool audience. This task was undertaken during the period 1990–1994 by the Early Window Project, a study conducted by John Wright and Aletha Huston and sponsored by the Center for Research on the Influences of Television on Children. In this 3-year longitudinal study, children's viewing habits were monitored through media use diaries, children were interviewed at each data collection point, and researchers administered a variety of tests to examine school readiness as well as math and reading achievement. Overall, those children who were regular viewers of *Sesame Street* demonstrated higher measures of language and math skills as well as school readiness. The children who participated in this study were also rated by their first schoolteachers, and those children who were regular viewers of educational programming were rated higher in terms of willingness to learn and school readiness.

In order to answer questions of long-term effects of *Sesame Street,* a follow-up study to the Early Window Project known as the Recontact Study was conducted by Wright and Huston with psychologist Daniel Anderson. During the early 1990s, this research team contacted participants in the original study, who had been 5 years old at the time of the study and were now between the ages of 15 and 19, to investigate the possible long-term effects of viewing *Sesame Street.* Among those contacted, 87% agreed to participate in the research project—a total of 540 participants. The findings demonstrated positive relationships between educational preschool program viewing and transcript grades in English, math, and science, and also demonstrated negative relationships between general entertainment viewing and the same transcript grades. These associations were much stronger for boys than for girls. Preschool educational viewing was positively correlated with creativity for both genders. This study is of particular importance to the research on educational programming, as it demonstrated the potential for positive long-term effects on school performance.

MISTER ROGERS' NEIGHBORHOOD

Whereas the original goal of *Sesame Street* was to promote the development of cognitive skills in preschoolers, the primary focus of *Mister Rogers' Neighborhood* was the development of social and emotional skills. This difference resulted in significant variations in production techniques between the two programs; for example, *Mister Rogers' Neighborhood* incorporated fewer cuts and was edited at a slower speed. One early study examined a group of 58 preschool children who were exposed to *Sesame Street, Mister Rogers' Neighborhood,* or another control program. The children in the study were observed while playing before and after their exposure to the programs. Small positive changes were apparent in the children who viewed either educational program, compared to the control group. Interestingly, the effects of the programs seemed to vary according to the IQ level of the children. Although there were no significant differences in those children with high IQs, children with average IQs who were exposed to *Mister Rogers' Neighborhood* were observed to be more cooperative with adults. This was not the case for the children with average IQs who viewed *Sesame Street,* who were observed to be less cooperative with adults after viewing. One possible explanation for this difference is that the faster pace of *Sesame Street* may have made it more difficult for some groups of children to understand its prosocial messages.

Researchers L. K. Friedrich and A. H. Stein conducted a series of studies based on *Mister Rogers' Neighborhood* during the 1970s. In the first study, published in 1973, 93 preschool children were divided into three groups: the prosocial group, who watched *Mister Rogers' Neighborhood;* the aggressive group, who watched *Batman* and *Superman;* and the control group, who watched nature and animal films. The children were observed during their free play for 3 weeks prior to the viewings, the 4 weeks of the 12 viewing sessions, and the 2 weeks following the viewings. The children who viewed *Mister Rogers' Neighborhood* showed numerous positive changes, including longer persistence on tasks, greater tendency to obey rules, and greater tendency to delay gratification. Moreover, viewers from lower socioeconomic classes also showed improvements in social skills such as cooperation and friendliness. Although these effects continued throughout the course of the study, they decreased during the 2 weeks following the viewings.

In a second study by Friedrich and Stein published 2 years later, the research agenda focused on whether children could apply the lessons learned from *Mister Rogers' Neighborhood* to their real lives, and on whether the effects would be stronger if viewing was accompanied by lessons relating to the prosocial skills

demonstrated on the show. Seventy-three kindergartners were assigned to view four episodes of the program and receive supplemental lessons in verbal labeling and describing as well as role playing with puppets. In the days following the viewing and lessons, the children's memories of the episodes and their willingness to help were evaluated. Researchers observed slightly more willingness to help in the children who had watched *Mister Rogers' Neighborhood.* For the boys in the study, the role playing appeared to reinforce the content of the programs. All the research conducted on *Mister Rogers' Neighborhood* was found to have positive effects, but the effects were stronger when viewing was accompanied by activities designed to emphasize the lessons within the program.

BLUE'S CLUES

Blue's Clues was developed as part of the Nick Jr. program block designed for preschool audiences in 1996. The program's design makes the fundamental assumption that children are intellectually active and willing to participate when they watch television. Although *Blue's Clues* owes much to *Sesame Street*, updated research and theory, with the help of researchers such as Dan Anderson, pushed the format a bit further and encouraged the active participation of the preschool viewing audience. The development of this program responded to parents' indication of a need—uncovered by Nickelodeon—for educational preschool shows. The main objective of the *Blue's Clues* curriculum is to enhance social and cognitive problem solving by engaging the children with problems during each episode.

Each episode takes children through the process of solving a problem, such as the steps necessary to find a lost item. During an episode, the host will frequently look directly into the camera and ask the viewers, "Will you help?" Episodes begin with the easiest tasks and become increasingly more difficult, so that all child viewers can feel challenged yet successful in solving problems and therefore remain engaged. The target audience for *Blue's Clues* is children 2 to 6 years of age. As one strategy for retaining the children's attention, the program mixes cartoon segments with live-action characters. Another strategy is the repetition of episodes, as each episode is shown for 5 days in a row during the Nick Jr. program block; this has been shown to greatly increase audience participation in the problem-solving segments of the program. In research by Daniel Crawley, Alisha Anderson, and colleagues, evidence from three experiments shows that experience with *Blue's Clues* teaches children that they can interact with television characters and with television programs in general.

DORA THE EXPLORER

Although little research on this program has been published by scholars, in the show's first year the animated series *Dora the Explorer* became the top-rated show on commercial television in 2001 for preschoolers aged 2 to 5 years. The main character of the show is a 7-year-old bilingual girl who lives in a cartoon fantasy world. The program is broadcast weekday mornings on Nickelodeon and Saturday mornings on CBS. The program design used throughout the series is a gamelike map that provides a guide to each segment. Each segment involves an adventure and a specific learning goal (such as counting, problem solving, and occasional use of words in both Spanish and English). Dora's companion, Boots the Monkey, provides friendship, and Swiper the Fox is also a regular character.

Clear directives, developed with the guidance of the program's research team, are incorporated both visually and verbally to help Dora achieve her goals. Although choices are provided, "magic" is often used (such as a blinking arrow) to lead Dora and the viewer toward the correct decision. Pauses are provided after each question so that the children who are viewing can try to answer before Dora says the correct response. This interactive element, designed to stimulate child participation and conversation, is best utilized when children and adults view together. Additionally, the same repetition strategy employed by Nickelodeon in *Blue's Clues* is also used in *Dora the Explorer.*

INFLUENCING POLICY

To the benefit of American children, the FCC was instrumental in passage of the Children's Television Act of 1990, which was not ratified until 1996 and which requires that all broadcast channels show a minimum of 3 hours of educational programming each week. At first, this regulation was only loosely employed, with broadcasters claiming that cartoons such as *The Jetsons* and *The Flintstones* contained educational values; however, many networks and cable channels more recently have begun to air good-quality, syndicated children's programming; some,

such as Nickelodeon, have also begun to produce their own programs. Initiatives of this type have the potential to benefit children tremendously.

CARTOONS, GENDER REPRESENTATION IN

Research focusing on gender representation in children's cartoons received some notable interest in the 1970s, with some follow-up in the 1990s, but it has not received much attention since that time. Current research indicates that gender stereotypes persist, although female characters are shown more often and in a greater variety of roles.

RESEARCH IN THE 1970s

The early research on gender stereotyping in cartoons arose out of the heightened gender consciousness generated by the second wave of the feminist movement. Three such studies were published in the mid-1970s. One of these studies found that many cartoons had only male characters and that this was particularly predominant in "chase-and-pratfall" (Looney Toon–type) cartoons. Typically, those females who did appear needed to be rescued. In "continuing adventure" (superhero) cartoons, females were presented stereotypically and tended to fall in love at first sight. The few female heroines frequently caused trouble for everyone in their paths. "Teachy-preachy" (Smurf-like) cartoons also had more male characters, but the female characters that appeared had more important roles than did the females in other types of cartoons. Overall, female characters were portrayed as less important and less responsible than males. Two other 1974 studies replicated these conclusions about the stereotypical presentation of female characters. One study found that female characters were slender and shapely, and males had 42 different jobs, but females had only 9. Females were never shown in positions of authority, but males were. The male characters were ambitious, competitive, knowledgeable, active, aggressive, sturdy, and bold. Females were passive, submissive, timid, emotional, and affectionate.

Research in the mid-1970s reached similar conclusions, finding that males outnumbered females on Saturday-morning cartoons. The male characters were portrayed in a greater variety of roles and occupations, whereas female characters were portrayed as housewives, mothers, girlfriends, grandmothers, maids, nannies, nurses, teachers, secretaries, waitresses, or witches.

STUDIES IN THE 1990s

Following up on this early research was a series of studies published in the 1990s indicating that female cartoon characters were outnumbered by male characters by four or five to one. A 1993 study of diversity in children's television indicated that adult minority females are invisible and that younger minority

females, when included, are presented as background characters or filler. Comparing pre- and post-1980 cartoons, Teresa Thompson and Eugenia Zerbinos's 1995 analysis of 175 episodes of 41 different cartoons concluded that male and female characters were shown stereotypically in both eras, although more so in the years prior to 1980. Overall, male characters were given more prominence, appeared more frequently, engaged in more of almost all the coded behaviors, and talked significantly more than did female characters. Males were more independent, assertive, athletic, important, attractive, technical, and responsible; showed more ingenuity; were more frequently the victims of both physical and verbal aggression; asked and answered more questions; expressed more opinions; emphasized task more; bragged more; and ordered and bossed others more. Females were more emotional, warmer, more romantic, affectionate, sensitive, frail, mature, and domestic; and more likely to ask for protection, to emphasize relationships, to be rewarded, to be helpless, and to praise. Male characters were never shown as caregivers and had jobs 31% of the time. Female characters were shown as caregivers 16% of the time but had jobs only 13% of the time. Chase-and-pratfall cartoons were typically more gender-role stereotypical than were teachy-preachy cartoons, and females in continuing adventure cartoons were least stereotypical but also appeared least frequently.

CHANGES OVER TIME

After 1980, cartoons tended to show more leads and minor characters of both genders, and female characters became more independent, more intelligent, and stronger; more assertive, competent, hardy, responsible, helpful, and guiding; and answered more questions. Female characters were less likely to complain, to be emotional, affectionate, or sensitive, and to show helplessness. Male characters after 1980 were likely to be portrayed as intelligent, technical, hardy, and verbally aggressive. Post-1980 male characters were also more likely to show leadership and ingenuity, to ask and answer more questions, to emphasize tasks, to express excitement, and to order and boss others. They were less likely to brag but tended to talk more than they had before 1980. Overall, then, significant change had occurred in the presentation of female characters, and some change had occurred in the presentation of male characters.

A 1995 analysis of sex-role stereotypes in children's cartoons in Hong Kong reported that male characters outnumbered female characters by 2 to 1. The female characters, however, were more common in the cartoons produced in Japan than in those produced in the United States or Great Britain. Male characters were more aggressive, rougher, sloppier, and stronger; females were more beautiful and more feminine.

More recently, research has indicated that male characters are still dominant in adventure and comedy cartoons. Male characters in adventure cartoons were more likely to use physical aggression, and female characters across all cartoon types were more commonly fearful, romantic, polite, and supportive. Another study found that, in the children's animated video series *Veggie Tales,* normative, predominantly male characters of nonspecific race occupied positions of authority and were portrayed as persons from whom one can learn important lessons.

The ever-popular Disney cartoons have also been the subject of inquiry regarding gender representation. These studies tend to use qualitative, critical methods rather than quantification and have argued that there has been little change in the gender representation of Disney characters from the early 1930s films to 1995's *Toy Story.* Males outnumber females, and females work in the home rather than outside of it, having little societal power. A recent analysis of Disney's *Pocahontas* reveals yet another model of female submission, however, in that Pocahontas ultimately subordinates her own desires to those of her community. It is argued that stereotypical representations of women have not changed but merely have been disguised. Others noted that *Beauty and the Beast* shows romanticization of men's control over and abuse of women. And a 2003 analysis of images of couples and families in Disney films reports that fathers are elevated and mothers are marginalized; rarely is power equally shared.

Of perhaps greater note than descriptive analyses of gender representation in cartoons, however, is the research that has examined the impact of such representation on children.

EFFECTS OF GENDER-STEREOTYPED PORTRAYALS

Socialization can be defined as a process through which children acquire the behaviors, skills, values, and social norms that are characteristic, appropriate, and desirable in their cultures. The media—through

its characters, storylines, and formal features—are important contributors to child and adolescent socialization, yet media portrayals are often stereotypical in nature. As summarized above, Thompson and Zerbinos found that children's cartoons, in particular, contained male characters who used aggression, demonstrated leadership qualities, and expressed opinions, whereas female characters tended to show affection, to ask for advice, and to engage in routine services. Such gender-stereotyped portrayals have the potential to shape children's beliefs about gender roles.

THEORETICAL FRAMEWORKS

Sex differences are of theoretical interest because young children are thought to develop sex-typed attitudes, preferences, and behaviors through observations of the world around them, including exposure to media messages. The development of sex typing occurs very early; children 3 years of age can make gender classifications and are aware of many social expectations. For instance, play with sex-stereotyped toys is one of the earliest manifestations of sex typing, with definite preferential patterns occurring before the age of 3. By age 4 or 5, children have acquired stereotyped occupational preferences and expectations.

Researchers working from the perspective of gender schema theory suggest that gender schemas (cognitive structures that guide our processing of information about males and females) help individuals choose behaviors that are "appropriate" for their sex. Social learning theorists suggest that children acquire sex-typed behaviors gradually, through observation of sex-typed patterns in others. They may also receive reinforcement or approval for "appropriate" sex-typed behaviors and punishment or disapproval for "inappropriate" sex-typed behaviors. Cultivation theory posits that the more time children spend watching television, the more likely they are to believe that what they see on TV accurately reflects their social worlds. Consequently, continued exposure to gender-stereotyped media portrayals can have powerful effects on learning what it means to be male or female.

THE IMPACT OF MEDIA ON GENDER-ROLE STEREOTYPING

Research conducted over the past 30 years, primarily focusing on television, indicates that repeated exposure to stereotypical portrayals in the media influences multiple gender-role outcomes. Much related research focuses discussion in four areas: (1) examining media's impact on gender-role stereotyping and flexibility, (2) gender-role attitudes, (3) viewer preferences for stereotyped activities and occupations, and (4) gender-related behaviors. In general, frequent television viewing is associated with stereotypical assumptions about male and female activities, traits, and occupations. Genre-specific effects have also emerged, with regular viewership of educational television and programming with nontraditional characters related to greater gender-role flexibility.

Although a substantial body of research examines the relationships between various types of television content (e.g., soap operas, action-adventures, music videos, advertisements) and gender-related outcomes (e.g., endorsements of stereotypes, perceptions of occupations), there is considerably less research examining cartoons or animation, a staple of children's television diets. One such example explored gender differences in children's emotional responses to, liking of, and perceptions of animated entertainment. The participants were 176 children aged 3 to 9 years. Children viewed short scenes from selected G-rated animated movies, and emotional responses and enjoyment were assessed; they were then shown previews from prototypical "female" and prototypical "male" animated movies. Emotional responses and enjoyment were assessed, and children were asked if they thought the movie was "a movie that mostly boys would like, a movie that mostly girls would like, or a movie that both boys and girls would like the same." Facial expressions were also videotaped and coded. In this study, the majority of children perceived the "male" preview (i.e., *Teenage Mutant Ninja Turtles*) as more enjoyed by boys, and few perceived it as more enjoyed by girls. In contrast, the majority of children perceived the "female" preview (i.e., *Beauty and the Beast*) as enjoyed by either gender. While the authors identified confounding variables that may have accounted for these findings (e.g., choice of stimulus may not have been prototypical enough, the movies differed on a host of characteristics), they also suggested that media viewers are more fluid in their interpretations of "female-oriented" programming than of "male-oriented" programming. Other researchers have similarly suggested that male gender roles are more rigidly defined than female gender roles.

PROGRAMMING TRENDS: ADULT-THEMED CARTOONS

Cartoons were once created with young audiences in mind, but this clearly is no longer a necessary viewer demographic. Adult-themed animation, such as *Family Guy* on the Fox network, a program containing a TV-14 rating and themes appropriate for adults, has attracted the attention and loyalty of children and adolescents. Programs such as these also contain information about gender attitudes, preferences, and behaviors, to name a few, yet it is unclear what messages a young audience might take away from this new genre of adult programming.

CARTOONS, HISTORY OF

Although cartoons are typically considered a genre for children, the history of cartoons in the United States reveals a complex relationship to multiple audiences (both adult and child) as well as to the film and television industries. Cartoons have historically used animation to both enhance and challenge popular conceptions of reality and experiences of modernity. Several early cartoons even revolved around tensions between "real" artists and their animated creations, who often sought to break free of their animators' hands (captured on celluloid with the cartoon drawn around it). Animators have often used anthropomorphized animals and unruly children as protagonists eager to challenge authority or affirm existing social values for audiences consisting equally of adults and children.

Additionally, cartoons quickly took their place in the realm of mass culture, forging early and lasting relationships with Hollywood. Successful cartoon characters, imbued with nonconformist personalities that appealed to an American public increasingly encountering anonymous work environments and mass distractions, became stars and were promoted and merchandised as heavily as any popular celebrity. The intense merchandising and often exuberantly violent behavior of many cartoon characters have repeatedly raised concerns regarding their effects on children, concerns that are helping to discursively construct that audience as in need of protection while imposing content restrictions on animation. Ironically, many of the early cartoons to come under fire were only debatably aimed at children. In fact, it was not until the arrival of television in the late 1940s that cartoons began to be separated from other genres and segmented according to industry assumptions about their audience.

CARTOONS IN THE EARLY 1900S

Although cell animation was first trademarked in 1914 by Earl Hurd, it did not become the industry standard until the early 1920s. Prior to this, animation was a very slow and costly process, as each frame had to be hand drawn and 16–24 frames per second shown. Cell animation allowed animators to draw only those aspects of the frame that were in motion, overlaying these transparent cells over static backgrounds.

The first successful animated cartoon is attributed to Windsor McCay, whose silent short *Gertie the Dinosaur* (1914) opened to critical accolades. McCay considered himself an artist, though, and the detail and planning that went into his work was not conducive to the development of an animation industry, which took on more of the factorylike qualities that would later describe other commercial art industries (such as comic books).

McCay was also the creator of the popular and innovative comic strip *Little Nemo in Slumberland* (1905–1911), about the nocturnal adventures of a dreaming child. Indeed, many early cartoons were adapted from existing comic strips. In 1915, William

Randolph Hearst established the International Film Service, an animation studio and distribution service intended to publicize and extend the merchandising capabilities of the comic strips owned by his syndicate. Charles Bowers, another early animation pioneer, bought the cartoon rights to *Happy Hooligans* and *The Katzenjammer Kids,* two popular strips, and entered into a partnership with Bud Fisher, creator of the *Mutt and Jeff* comic strip. These and many other early cartoons featured naughty children and out-of-control animals in adventures that challenged social norms. Although inevitably punished for their transgressions, these irrepressible protagonists allowed audiences to take pleasure in their law-defying behavior, acceptable because of the characters' childlike personalities.

One of the early successes from Max and Dave Fleischer, whose animation house would rival Disney's throughout the 1930s, was Koko the Clown (1920). Koko's adventures often began with Max Fleischer's hand appearing in the frame drawing the character, who would then engage in an ongoing battle with his creator. Appropriately, the series, as well as the Fleischers' initial production house, was named Out of the Inkwell, Inc. In every Koko cartoon, the ink bottle served as a figurative prison or womb from which Koko would emerge. In one adventure, Koko grows to the size of a giant and wreaks havoc on an animated New York City while searching for Fleischer (*Bedtime,* 1923). In *Koko the Cop* (1927), Fleischer frustrates Koko's attempts to run away by pulling the camera back to reveal that he is running on a long strip of paper that the artist is turning on a treadmill. While the series drew its humor from exaggerating the public's anxiety about self-determination in the wake of the Industrial Revolution and the emergence of corporate capitalism, Koko's popularity made the figure particularly appealing to corporations seeking celebrity endorsement. In 1927, Koko appeared in a film sponsored by AT&T called *The Little Big Fellow's Voice,* followed in 1929 by the Westinghouse-sponsored *Finding His Voice.* Both films were designed to sell new telephone and radio technologies to adult consumers.

Further evidence of the adult audience for animation might be found in the success of the Fleischers' non-Koko production, *Einstein's Theory of Relativity,* praised by critics (as well as by the scientist) and designed to imaginatively explain complex scientific discoveries to viewers. Interestingly, the Fleischer follow-up, *Darwin's Theory of Evolution,* released in 1924, was met with considerable controversy and disapproval from the Church, leading to the discontinuance of the series.

Perhaps the most popular silent animation "star" was Felix the Cat, created by Otto Messmer for Pat Sullivan Studios in 1919. Felix became the prototype for animal characters with human traits, which multiplied during the next few decades and included Mickey Mouse and Bugs Bunny. It is rumored that Felix drew his inspiration from Charlie Chaplin, whose childlike excitement and innocence Felix imitated along with the comedian's famous movements and mannerisms. Like Koko, Felix often took advantage of his animated status to manipulate his surroundings. Felix's tail could stretch and take different shapes at will. Unlike Koko, Felix usually maintained the upper hand and rarely fought his creator for supremacy. Instead, Felix could make reality bend to his creative whim. Charles Solomon estimates that, at the height of Felix's popularity in the 1920s, three quarters of the world's population could recognize the character. A successful line of toys, dolls, and other merchandise was launched in 1926, netting Sullivan an estimated $100,000 a year.

THE GOLDEN AGE OF ANIMATION

The years 1928–1941 are generally considered the golden age of animation, thanks in large part to the emergence of Walt Disney and the creative work done at Warner Brothers animation studios. Disney and Warner Brothers were rivaled by the Fleischers during this period as well, whose exclusive distribution deal and later takeover by Paramount Pictures gave them tremendous exposure. The rise of Disney and the decline of the Fleischers has much to do with the imposition of censorship on animation and growing assumptions about animation's intended audience.

Following and eclipsing their success with Koko the Clown, the Fleischers created Betty Boop, the sexually suggestive yet chaste flapper, and her boyfriend, Bimbo the Dog. The libidinous relationship between Betty and Bimbo made many of their early adventures decidedly adult. Fleischers' other success was actually adapted from E. C. Seger's newspaper cartoon, *Thimble Theatre:* Popeye the Sailor. Popeye and Bluto's endless blowouts over the affections of the fickle Olive Oyl made most cartoons featuring these characters little more than extended fight scenes. Yet, the creativity of the animation and the sheer pleasure of watching grown men behaving badly with no

regard for social etiquette made Popeye cartoons crowd pleasers. Indicating their awareness of what made Popeye so successful, *It's the Natural Thing to Do* (1939) begins with the characters receiving a telegram from a fan admonishing them to "act more refined." Popeye, Olive, and Bluto proceed to get dressed up and attempt to have a quiet tea party, but their bumbling attempts at elegance quickly degenerate into an all-out brawl. At cartoon's end, Olive proclaims their retreat to formulaic violence "the natural thing to do."

While the Fleischer brothers reveled in parodic interpretations that stretched the boundaries of reality and the limits of social mores, Walt Disney was moving in entirely different directions. Although Disney's animation efforts trace back to the early 1920s, 1928 marks the debut of the character most associated with the company: Mickey Mouse. Cartoon historians have noted similarities between Mickey, Bimbo, and Felix the Cat. Yet, Disney would take his mouse in entirely different directions. Mickey debuted in *Steamboat Willie,* the first successful effort to combine sound and animation. Disney took cartoons to new heights, beginning with the debut of his *Silly Symphony* shorts in 1929, and culminating in the release of *Fantasia* in 1941, a feature film that visually told the stories of classical symphonic musical pieces. (Disney also experimented with color, signing an exclusive 2-year deal with the creators of Technicolor in 1932, which contributed to *Flowers and Trees* winning the first-ever Academy Award for an Animated Short later that year.) Although *Fantasia* was a flop that nearly bankrupted Disney, it is the key to understanding Disney's conception of his audience in classed and parental terms. The film subsequently gained a huge cult following through rereleases and the advent of video.

Even though Mickey Mouse was incredibly popular and heavily merchandised to children (by 1931, there were already an estimated 1 million members of the Mickey Mouse Club), the Disney promotional machine also went out of its way to stress the mouse's adult devotees as well, who included such luminaries as Franklin Delano Roosevelt and Benito Mussolini. As Mickey's popularity grew, his adventures became tamer, and he eventually became a "straight man" for other Disney characters. In 1935, Mickey was proclaimed an international symbol of goodwill by the League of Nations. The careful management of Mickey's image as both appealing to adults and safe for children (Disney proclaimed the character "so simple and uncomplicated, so easy to understand that you can't help liking him") was quite different from the Fleischers' promotion of the irreverent Betty Boop and Popeye characters.

Mickey's merchandising mania was both a sign of the character's appeal and of Disney's need for revenue. Disney's studio created the most expensive cartoons in the business, emphasizing a painstakingly realistic animation style that required employing hundreds of cartoonists and took far longer to produce than the works of his competitors. In an era in which a 6-minute cartoon cost, on average, $5,000 to $7,000, Disney's shorts came in at between $37,000 and $50,000. Foreseeing changes in how cartoons were exhibited, Disney set out to create the first full-length animated feature in 1937, *Snow White and the Seven Dwarfs,* at a cost of $8 million. Disney also established a 3-year production schedule for his subsequent features (*Pinocchio* [1939], *Fantasia* [1940], and *Bambi* [1941]), which allowed high production values but also placed the company in tremendous debt as it shrugged off short-term profits in favor of long-term success. *Snow White* also fit Disney's grandiose vision of creating high-quality animation that stressed both realism and lyricism. Disney films aimed to be high art rather than social parody. *Snow White* was one of the first to sustain a coherent narrative from start to finish (most cartoon shorts relied on a series of gags).

The third most successful animation house of the golden era was run in house by Warner Brothers Studios and featured the talents of Tex Avery, Chuck Jones, and Mel Blanc. Their creations were also derivatives of the successfully anthropomorphized Felix the Cat, and their short series, *Looney Toons*, was a direct attempt to build on Disney's *Silly Symphonies* success. However, Warner Brothers' cartoons were often far more willing to poke fun at both high and low culture than those of either Disney or Fleischer. Their shorts were highly intertextual and self-referential. Although such elements existed in cartoons prior to Warner Brothers', their high profile and established distribution network allowed characters like Porky Pig, Bugs Bunny, Daffy Duck, and others to gain national notoriety. Like Disney, Warner Brothers intended its cartoons to appeal to both children and adults, combining gags with pop culture references that stimulated audiences on multiple levels. Disney used high art aesthetics with fairy-tale stories to achieve a similar effect.

Until the late 1940s, most Hollywood films were released through vertically integrated studios that controlled production, distribution, and exhibition networks. To keep their theaters in constant supply and to attract audiences during the Depression, most studios supplied their theaters with double features and other short materials, which included newsreels, serials, B-Westerns, and cartoons. Most animation studios were either directly under studio control or had exclusive distribution deals with them. However, in 1948, the U.S. Supreme Court ruled in *United States v. Paramount Pictures* (also known as the Hollywood Antitrust Case of 1948) that vertical integration was a form of monopoly. The ruling forced the studios to divest themselves of their exhibition networks. This separation of the studios from the movie theater chains led to a drastic reduction of materials produced.

TELEVISION CARTOONS

The *Paramount* verdict led to the closure of many animation studios that could no longer find distribution and exhibition networks for their products. Others switched media and began focusing their attention on the emergent technology of television. In fact, the majority of early television cartoons were simply recycled movie shorts clipped together around an enigmatic host. Although the format was first introduced by Van Beuren Productions in the early 1940s, which syndicated their catalog of cartoons to independent stations, the bigger studios did not jump on board until the early-to-mid 1950s. Still, the immense need to fill broadcast hours and the proven track record of these materials eased the transition. Characters such as Mickey Mouse, Bugs Bunny, and Popeye, although not originally created for television, found renewed (and larger) audiences there than they had in movie theaters. In economic terms, it made sense to recycle these shorts onto television. Disney used Mickey Mouse cartoons as filler and as attraction for his television series *Disneyland.* The cartoons sold the series, and the series, in turn, served mostly as a promotion for the development of the theme park.

Of course, television functioned somewhat differently than had motion pictures. Whereas films had to assemble a collage of materials designed to appease entire families, television could designate specific hours of the day to show cartoons. Although Betty Boop and Popeye were often censored more heavily under FCC regulation than they had been in movie theaters, the changes were not so much in terms of content as in the ghettoization of cartoons. The scheduling of cartoons reflected the assumption that children were the primary audience for cartoons.

New materials for television did not follow Disney's lead in terms of naturalistic aesthetics. The need to produce quickly and cheaply, coupled with the influence of abstract expressionism in post–World War II art, led to an animation style that emphasized flattened perspectives, abstract and minimalist backgrounds, limited and oft-repeated character movement, and fewer individual frames per second. Moreover, television cartoons demonstrated the medium's radio heritage by placing greater emphasis on dialogue than on visual storytelling, often using dialogue to reinforce a visual pun. United Productions of America led the way with the introduction of Mister Magoo in 1949, again into syndication. The first network-produced, made-for-TV cartoon was *The Ruff and Reddy Show,* which debuted in 1957. It was the first project of Hanna-Barbera Studios and is considered the first Saturday-morning cartoon.

Although television contributed to the segmentation of cartoon audiences, it would not be long before the genre's adult potential would be exploited. Hanna-Barbera's *The Flintstones* debuted in prime time on ABC in 1960. Although it presaged the contemporary appeal of adult-oriented animation on television, its success must also be situated within the larger historic appeal of cartoons to multiple audiences. Although set in the Stone Age, the series' characters drew inspiration not from contemporary American families but from their representation on television in the series *The Honeymooners* (1955–1956). In this regard, it might be argued that the appeal of the series lay simultaneously in its nostalgic recalling of a golden-age television series and in its parodic undermining of it, which simultaneously reinscribed and questioned the "normalcy" of the American nuclear family. The series was also the first continuous, 30-minute animated television series.

Although *The Flintstones* appealed to adults, it was also successfully merchandised to children (the show's multiple audience appeal is evident in the ease with which it switched over to a Saturday-morning slot on NBC in 1967 following its prime-time run on ABC from 1960 to 1966). In fact, one of the earliest controversies involving children and television animation centered around the commercials selling Flintstones vitamins that accompanied the series. The

argument that children could not distinguish the ad from the series led to the pulling of the spots, although the Flintstones continued to sponsor other products, including breakfast cereals and clothing lines. Adding to the confusion about where the show ended and the commercial began was *The Flintstones*' simultaneous appeal to both children and adults. At around the same time that Fred Flintstone and Barney Rubble were hawking children's vitamins, they were also acting as animated spokespeople for Winston cigarettes.

With FCC deregulation in the 1980s, Saturday-morning cartoons became sources of even greater controversy among parents, who feared both their excessive commercialization and their violence. Series like *Strawberry Shortcake* (1981–1984), *He-Man and the Masters of the Universe* (1983–1985), and *The Pac-Man/Donky Kong Hour* (1982–1984) took the established merchandising strategies of previous cartoons and turned them on their heads. Each series was developed after an existing product line had already been developed and explicitly used the cartoons to introduce new toys, costumes, and other commodities. Additionally, accusations soared that cartoons were becoming increasingly violent in their content. This is certainly a supportable allegation, given the popularity of shows such as *G.I. Joe* (1985–1986) and *The Transformers* (1984–1987) during the 1980s, series that featured war as their central theme and centered around remarkably deathless destruction (*G.I. Joe* cartoons featured the destruction of several fighter jets in every episode but always showed the pilot parachuting to safety).

CONTEMPORARY CARTOON PROGRAMMING

In 1989, *The Simpsons* (1989–) made its prime-time debut, spinning off from *The Tracey Ullman Show.* The series is a flagship for the Fox television network and marked the wide-scale emergence of adult-oriented animation on television in general. Far more referential and intertextual than their predecessors, contemporary prime-time animation shows have been more willing to overtly court controversy and challenge established values than have previous incarnations. Series such as *South Park* (1997–), airing on cable (freeing it from already-relaxed FCC guidelines for broadcast networks) and using computer animation that allows rapid production, are able to parody political events almost immediately after their occurrence. In 2005, *South Park* responded to the Terri Schiavo controversy (over the moral and ethical implications of ceasing her life support) with an episode in which Cartman defends Kenny's right to death (the episode's humor is derived through multiple layers: the direct referencing of the Schiavo case, still being discussed on national television when the episode aired; the use of children as wise-beyond-their-years yet cynical commentators on contemporary mores; and the fact that every previous episode of *South Park* had featured Kenny's death through increasingly bizarre circumstances that went almost unnoticed by the other characters, for whom death and destruction on television had become routine). Like other adult-oriented animated series, *South Park* remains purposely ambivalent in its politics, preferring to poke fun at both authority and resistance to it, appealing to cynical audiences on both ends of the political spectrum.

The Simpsons and *South Park,* along with *Family Guy* (1999–2001, 2004–), *American Dad* (2004–), and other series, often situate their satire within nuclear families and use children as their central commentators (and usually the voices of reason), with adults typically depicted as buffoons who are quick to judge and easily duped. This suggests that the appeal of these series might also rely on generational humor that pokes fun at the baby boomer generation while affirming the open-minded, color-blind, apolitical values of generations X and Y. Such audiences also continue to watch reruns of Hanna-Barbera cartoons on cable networks such as Cartoon Network and Nickelodeon through increasingly nostalgic yet cynical lenses, reading series like *Scooby Doo* (1969–1993) as containing covert drug references and other countercultural themes yet still depicting a far less complicated world than the contemporary one. Tellingly, when Cartoon Network launched its Adult Swim block in 2001, it used the series *Space Ghost Coast-to-Coast* (1994–) as its cornerstone. *Space Ghost* recycles a lesser-known, late-1960s Hanna-Barbera superhero as a talk show host, purposely calling attention to both the bizarreness of the genre blending and the amusingly inane yet harmless characters.

In fact, Comedy Central's success is perhaps most indicative of the direction television cartoons are headed. Launched in 1992 by Ted Turner, the cable network was intended to take advantage of the synergistic potential of media conglomerates. In 1991, Turner purchased Hanna-Barbera's library, adding it to the MGM Tom and Jerry cartoons and Warner

Brothers' pre-1950s cartoon library that he had already acquired. Not surprisingly, the earliest fare on Cartoon Network was repackaged classics. Original programming began in 1994. In 1995, Turner Broadcasting Systems merged with Time Warner, Inc., expanding the network's exposure and profile while also leading to increased synergies. Time Warner, Inc. owns DC Comics, and the Cartoon Network has been the launching ground for several superhero adaptations based on DC properties, including *Superman: The Animated Series* (1996–2000), *Justice League* (2001–), and *Teen Titans* (2003–). The network's popularity has grown rapidly from an estimated 12.4 million viewers in 1994 to 80 million in 2002. Although its core target audience is children aged 2–11, Cartoon Network has also successfully attracted a more lucrative "tween" audience (ages 9–12) with disposable income and desperate to join the ranks of adolescent consumers. Additionally, one third of Cartoon Network's audience are adults aged 18–34. Many are parents, yet others are attracted by the network's nostalgic fare marketed through contemporary cynical sensibilities. *The PowerPuff Girls,* created in 1998, combine postfeminist notions of girl power, psychedelic animation, and relentless merchandising. In 2000 alone, PowerPuff merchandise exceeded $350 million. As of 2003, Cartoon Network is the eighth largest advertiser-supported basic-cable network on television.

Since the mid-1990s, animated feature films have also made a comeback as new computer graphics imaging technologies have allowed more complex graphics that offer a greater degree of verisimilitude. Whereas *Snow White* aimed for a lyrical realism, contemporary films such as *Toy Story* (1995) and *The Incredibles* (2004) often intentionally play upon the realistic movements and settings of their animated characters, making the juxtaposition part of the pleasure. Contemporary motion pictures are still designed to please multiple audiences through intertextual dialogues and imagery. *Toy Story* showcases a wide variety of play objects that evoke nostalgia among adult generations (Woody is a talking cowboy doll, Mr. Potato Head, is, well, a Mr. Potato Head, and even Buzz Lightyear, the supposed "next generation" of toys, is more reminiscent of 1980s action figures than of contemporary video games). Still, contemporary film animation remains controversial for similar reasons, as did its predecessors. Accusations of violence and blatant merchandising are often accompanied today by concerns over gender and race representations, signaling the increased media savvy of today's audiences. Disney's *Pocahontas* (1995) was accused of whitewashing Native American history, ignoring historical atrocities while rendering Pocahontas as an Indian Barbie doll.

CARTOONS, VIOLENCE IN

Parents and watchdog groups have cried out against the amount of violence in children's programs for years. However, others feel that violence in cartoons has little effect on subsequent behavior because cartoons show fantasy violence and are far removed from real life. In general, research has supported the belief that viewing violence in cartoons *does* have an effect on children's subsequent aggressive thoughts and behavior. The effect is strongest among very young children (under age 7) who may have difficulty differentiating between fantasy and reality. Most adults and older children realize that Superman

cannot actually fly and that the monsters in *Pokémon* are not real. However, very young children may believe that, if they put on a cape and jump off the couch, they will soar through the air, or that the monsters they view on television are real and are hiding under their bed ready to bite their ankles should they carelessly let a foot fall over the side. Because the television characters young children view each morning are very real to them, they are more likely to imitate the behavior they see.

Several research groups over the last few decades have analyzed the content of children's television programming to discover the amount of violence and the contextual features of children's cartoons. The prevalence of violence in cartoons has changed over time; however, methods and sampling techniques have varied considerably from study to study. In the late 1960s, Leonard Zusne found that nearly 6% of the total time in a sample of 64 cartoons was spent engaging in violence. In the late 1970s and early 1980s, George Gerbner and his colleagues made extensive analyses of the violence in children's programming and found that children's programs were consistently more violent than any other genre. On average, 90% of children's television programs contained violence, compared with 70% found in mainstream programs. This finding remained stable in the early 1990s, with cartoons being the most violent programs, compared with 16 other genres.

The most recent and extensive study on violence in children's television programming was conducted by Barbara Wilson and colleagues as part of the National Violence Study. Overall, 69% of children's television programs contained violence, compared to 57% found in other programming. Violence aimed at children was more likely to be portrayed in a humorous context, and it was less realistic than in other programming. Aggressors were less likely to be punished for their actions, and short- and long-term consequences were often absent. All these contextual variables have been shown to increase the likelihood of imitation of violence witnessed on television. On a positive note, children's programs were less graphic and were less likely to show gun violence than were other programs.

As in earlier research, Wilson et al. split up children's programming into several subtypes and found marked differences in how violence was portrayed in each category. According to Wilson et al., slapstick programs (e.g., *Tom and Jerry, Looney Toons*) are the most troubling in terms of increased risk of imitation. These are programs that involve anthropomorphized characters who engage in off-the-wall antics. The plots are usually simple and repetitive, and they often involve large chases or games that defy the law of physics. For example, imagine Wile E. Coyote and the Roadrunner from *Looney Toons,* in which each cartoon is a farcical chase that involves exploding dynamite, falling grand pianos, and giant slingshots. One hundred percent of slapstick cartoons contained some form of violence, and a child watching this type of program can expect to see a violent act every 2 minutes. Violence in these programs shows a very unrealistic level of harm, is often portrayed as justified, and is cased in humor. These programs may be particularly harmful for very young children, who may have difficulty separating fantasy from reality.

Superhero programs (e.g., *Batman, Spiderman*) are nearly as violent as slapstick ones. As the name suggests, these programs involve characters with fantastical powers such as the ability to fly or to become invisible, who often use violence to save the day from the bad guys. Ninety-seven percent of these programs contained some violence, with a violent incident nearly every 2 minutes. Violence in superhero programs is also problematic, as it is portrayed by attractive heroes who use justified violence to save the world. The heroes are almost always rewarded for their violent actions, and guns and other weapons are more likely to be seen in this subtype than in other children's cartoons. This potent combination makes these programs particularly risky for subsequent imitation by viewers.

Mystery and adventure programs (e.g., *Scooby Doo, Goosebumps*) contain about half the amount of violence of slapstick and superhero programs. Although 90% of programs still feature some violence, the plot is likely to focus on solving a riddle or a problem instead of physical confrontation.

The last two categories, social relationship programs and magazine programs, contain much less violence than the previous examples. Social relationship programs (e.g., *Rugrats, My Little Pony*) focus on getting along or working out problems among a group involving friends, family, or peers. Only about 50% of these programs contain violence; the violence that is portrayed is commonly less lethal and more likely than other programs to show the consequences of violence. Magazine programs (e.g., *Blue's Clues, Sesame Street*) are by far the most innocuous. These programs feature a series of short segments involving, skits, stories, or songs. The programs are often "educational," and fewer than 20% contain violence.

One type of cartoon not represented in Wilson et al.'s study is anime, cartoons based on Japanese animation. This is because anime did not air on American television until 1998, one year after Wilson and colleagues' study. When first introduced, *Pokémon,* an anime cartoon featuring little "pocket monsters," immediately became the number one children's program in syndication. The popularity of *Pokémon* spurred a number of anime-like programs, including *Digimon, Dragon Ball Z,* and *Inuyasha.* These programs have been criticized for containing unusually high amounts of graphic violence. Time will tell what impact these incredibly popular and violent programs will have on children's development.

Violence in cartoons is often varied and depends on the subtype examined. However, as a whole, violence in cartoons is marked by its lack of consequences and by humorous presentation that can trivialize the seriousness of violent behavior. Such portrayals have vast implications for society as a whole because they may teach young children that violence is an acceptable answer to any problem they face.

CATHARSIS THEORY

Catharsis theory dates back to ancient Greece, when Aristotle suggested that art can have a cathartic (cleansing) effect by allowing us to experience powerful emotions such as pity and terror without having to go through the real-life events that would give rise to such feelings. Catharsis theory has changed since Aristotle's time; modern proponents suggest that it means that people, including children, can use various media (movies, television, video games) as ways to vent inappropriate urges or emotions in safe, socially acceptable ways. For instance, instead of acting out violently against peers, a child can play a video game that allows violent behavior to be purged, hopefully preventing violence from ever manifesting in a real encounter. However, most research on media effects, particularly regarding children, contradicts catharsis theory and suggests that the detrimental effects of media depicting undesirable behavior outweigh any cathartic function.

The origins of contemporary catharsis theory can be traced to Jacob Bernays, who in 1857 suggested that there was a psychological benefit to getting rid of unhealthy emotions or urges. Bernays said that one way to purge these feelings was through the consumption of art or media that contained similar themes (for instance, violent art to purge feelings of anger or violence). Not to flush out these bad emotions through catharsis, said Bernays, could lead to the kind of psychological maladies that his distant relative Sigmund Freud popularized during the same era.

Since Bernays's time, other media theorists have attempted to promote catharsis theory. In the 1960s and 1970s, Seymour Feshbach advanced catharsis theory through a series of experiments that examined the psychological states of subjects who consumed cathartic media. For the most part, however, a growing body of media effects research weighs in against catharsis theory, especially catharsis in children. Many recent studies find that children who consume a particular kind of media are more likely to imitate the behavior depicted in the programming than are children who watch something else. Such a result is the opposite of what catharsis theory suggests would occur (a decrease in the behavior viewed attributable to a catharsis effect).

For example, a 1995 study of children's behavior after viewing *The Mighty Morphin' Power Rangers* found that children who watched the program in an experimental setting demonstrated seven times as many physically aggressive acts toward other children during playtime as did those who did not watch the Power Rangers before playing. If the violent content of the aggressive cartoon served to purge similar tendencies in young audiences, as catharsis theory would suggest, then watching the Power Rangers should result in fewer, not more, aggressive acts in children.

However, it should be noted that the influential effect of media content can be used for positive ends as well. In her 2001 doctoral dissertation at the University of Melbourne, Katrina Skewes found evidence that, for bereaved adolescents, group therapy using the cathartic function of music was successful in improving the mental condition of the subjects.

Most of the current research that undermines catharsis theory was not conducted with catharsis theory in mind. Instead, many of these studies were conducted to test support for social learning theory, which suggests that many behaviors can be "learned" socially by watching others perform them. If those seen displaying the behavior are somehow rewarded for it, social learning of the behavior is said to be encouraged. For the last 20 years or so, social learning theory and catharsis theory have been positioned in near perfect opposition to each other as researchers attempt to explain the implications of mediated depictions of undesirable behavior. For now, a growing body of evidence seems to contradict catharsis theory.

CENTER FOR MEDIA EDUCATION (CME)

The Center for Media Education (CME) was a Washington, D.C.-based nonprofit organization that represented the interests of families and children in national media policy debates. Cofounded in 1991 by Kathryn Montgomery, a former professor at the University of California at Los Angeles, and Jeffrey Chester, a filmmaker and activist, CME became best known for leading a series of successful, high-profile policy campaigns during the 1990s.

The group's 1992 report on broadcast failure to comply with the 1990 Children's Television Act sparked a major public debate about quality in educational programming and prompted the Federal Communications Commission to conduct a formal proceeding on the issue. CME organized a coalition of child advocacy, health, and education groups in a 4-year effort to strengthen the implementation rules, resulting in a 1996 rule requiring TV stations to air a minimum of 3 hours of children's educational programming per week as a condition of license renewal. In 1997, CME led a coalition of groups in negotiations with leaders of the television industry to amend the TV Parental Guidelines, which had been developed to work with the congressionally mandated V-chip. As a result of these efforts, content descriptors (V, L, D, S, FV) were added to the age-based television ratings. CME's 1996 report, *Web of Deception,* alerted parents, policymakers, and the press to potentially harmful marketing and data collection practices targeted at children and teenagers on the World Wide Web. CME partnered with the Consumer Federation of America, as well as other child advocacy and privacy groups, to petition the Federal Trade Commission to institute rules to safeguard children's privacy on the Internet. This work led to passage of the Children's Online Privacy Protection Act (COPPA) in 1998.

CME was also centrally involved in policy efforts to promote equity and access in the new digital media, cofounding the Telecommunications Policy Roundtable, a coalition of civil liberty, education, and computer groups that advocated the "Public Interest Principles for the Information Superhighway." CME worked closely with national education and library groups to encourage their involvement in congressional deliberations on the Telecommunications Act of 1996, resulting in the creation of a federal fund (often referred to as the *e-rate*) to provide affordable

access to the Internet for schools and libraries. In partnership with the University of Texas, the CME organized a major national conference in 1998, bringing together leading figures in the academic and commercial sectors to address the issues of quality, research, and access in children's new media. The conference helped lay the groundwork for the establishment of the National Science Foundation's Children's Digital Media Centers.

In 2003, when Kathryn Montgomery returned to full-time teaching at American University, the CME closed its doors, transferring its research initiatives to American University as part of the new Youth, Media and Democracy Project in the School of Communication. The project's 2004 report, *Youth as E-Citizens,* documented the variety of ways that adolescents and youth were using the Internet for civic and political engagement.

CHAT ROOMS

Use of online chat rooms by children and teenagers has received a great deal of media attention. Although the primary focus has been on the perceived risk to children of contact with pedophiles in this environment, chat room use also has some positive aspects.

There is some confusion over the term *chat room* in popular usage. Although the term is sometimes used to describe any form of non-email message exchange, the term is used in this entry to refer to a shared online space in which two or more people communicate simultaneously. It is distinct from instant messaging (IM) because the latter is designed primarily around one-to-one communication with known others (although some IM software includes chat-roomlike features).

According to a U.S. survey of Internet-initiated sex crimes against minors reported by Wolak, Finkelhor, and Mitchell, 76% of initial approaches came through chat rooms. However, such crimes rarely correspond to the media stereotype of the prepubescent child lured to an innocent meeting and abducted. Of all crimes identified in the survey, only 1% were committed against 12-year-olds (75% of them female), although 26% were committed against 13-year-olds, 22% against 14-year-olds, and 28% against 15-year-olds. The offenders did tend to be considerably older; only 1% were under 18, 23% were 18–25, 41% were 26–39, and 35% were 40 or over. However, only 5% represented themselves as teenagers (a further 25% shaved a few years off their ages), and 84% of cases did not involve coercion. Four out of five offenders brought up sexual topics during online communication with victims.

Although an increasing number of large companies hosting such chat rooms have either regulated them or shut them down, large numbers of unregulated chat rooms remain, as does Internet Relay Chat, which uses an open standard and is highly fragmented and therefore very difficult to regulate. Talking to strangers in chat rooms is one of the behaviors most likely to be banned by parents (along with giving personal information and meeting strangers face to face). Chat room use tends to be more prevalent (and riskier) among adolescents than among younger children, and there is some evidence that children who use chat rooms are more likely to come from difficult environments and to practice other risky behavior. Chat rooms are not, however, a particularly popular use of the Internet, even among young people. A United Kingdom survey of 9-to-16-year-olds found that 18% accessed chat rooms (O'Connell, 2003), and a NetRatings Australia survey of 8-to-13-year-olds with home Internet access found that 16% of girls and 20% of boys accessed chat rooms, whereas IM was practiced by 44% of girls and 36% of boys. Chat rooms specifically aimed at teens are often popular hangouts, and they participate over a range of topics—often self-help and peer support or music-based rooms.

It is hard to assess the overall risk to young people from unwelcome face-to-face contact driven by chat, but the potential psychological harm from strictly online interaction is a more widespread danger. In a survey of 1,500 U.S. youths (ages 10–17) who went online at least monthly, almost one in five had received an unwanted sexual solicitation online—one in four of which made them "very or extremely afraid."

Comparatively little research has been done on the practices or benefits of online chat outside of the harms outlined above. However, Danet has studied how Internet Relay Chat was used in a creative fashion to improvise artistic performances online, and, more generally, a number of authors—Turkle prominent among them—have suggested that adolescents can benefit from using online experimentation to explore and develop their identities. Because online communication lacks physical cues, it can be easier for children to overcome embarrassment and talk to their peers or to adults in chat rooms, and this can help them practice their social skills.

CHAT ROOMS, SOCIAL AND LINGUISTIC PROCESSES IN

When *face-to-face communication* takes place, there is co-presence: The participants are in the same place at the same time, using both speech and nonverbal messages to make themselves understood. Those communicating in *computer-mediated chat,* or *online chat,* on the other hand, are separated geographically but logged in simultaneously to a virtual chat room. They are making themselves understood by typing messages quickly onto a keyboard; online chatters alternate rapidly, and the chat program shows the successive contributions on the computer screen. Online chat is written conversation. Like face-to-face conversations, it can take place as a dialogue or in a group.

The term *chat room* usually applies to *webchat*, in which chat rooms are accommodated on Web servers and can be used by means of a Web browser; a chat room is basically nothing but a window appearing on the screen. There are also graphical chat systems in which the chatters can move as *avatars* (graphical representations like cartoon characters or photos) through a pictorial scene such as a living room or forest or discotheque (the Palace at www.palacetools.com is an example). Although there are many chat rooms with unrestricted topics, basically for small talk (*off-topic chat rooms*), others are dedicated to particular themes, target groups, or purposes, which are usually clear from the name adopted for the room (*on-topic chat rooms*).

Internet Relay Chat (IRC) is communication made possible through networks of servers that allow group communication in discussion forums called *channels*. The processes of communication in webchats are often difficult to capture for documentation purposes, but those in IRC channels can be automatically logged on the IRC "client" (the program used to connect to the server). As a consequence, sociological and linguistic studies of the chat process relate in many cases to IRC. However, the results are normally transferable to webchatting.

According to a Pew Internet & American Life Project study described by Lenhard, Rainie, and Lewis, more than half the 12-to-17-year-old Internet users in the United States (55%) were users of chat rooms in 2001; the figure for adult users was about a quarter, at 26%. Male and female teenagers are equal in their love of chatting. It is more common for the 15–17 age group to chat than for the 12–14 age group. The figure for those visiting a chat room among young people using the Internet daily is as high as 62%. Although chatting is less common among North American teenagers than email (used by 92%), it is still more popular than creating one's own homepage (24%). For individual countries, the chatter statistics require separate analysis.

SOCIAL PROCESSES IN CHAT ROOMS

Before entering a chat room, one has to select a *chat name* or nickname; in the case of graphic chat rooms, the user also needs to select an avatar. The choice of nickname (e.g., "tom_17," "eminem-fan," "Barbiedoll_14) may communicate such identification marks as gender, age, and interests, and may also indicate motives for the communication. On entering a chat room, the user announces his or her arrival and then joins the ongoing conversations. Because the chatters are not physically present in an actual room, words of greeting are important. Chatters who have "met" previously address each other by name, and generally users say "hi" or give verbal hugs. If there are lots of chatters in a room, there will be different chat threads running in parallel, and beginners will find it hard to get a clear picture. It takes time to work out the different threads and to address individual chatters by name (e.g., "tom_17: where are you from"). Also, a distinction has to be made between pauses in chatting caused by the system and socially determined periods of silence.

The invisibility of online chatters necessitates an initial exchange of basic information when a conversation is started with an unknown person. This verbal questioning is redundant in face-to-face meetings. If the nickname has not already revealed the details, an *ASL check* (age, sex, location) takes place, and a possible reply would be "w/16/texas." It is, of course, not absolutely necessary that these and other identifying details given in chat reflect reality exactly. Online chatters occasionally change their reported sex, physical appearance, or—even more commonly—their age. Young teenagers are particularly eager to appear older. Some chatters construct outright fake identities for themselves. However, playing with virtual identities meets its limits when chatters are not interested in mere online chat sessions but wish to develop longer-term and more serious contacts with other chatters. That makes it difficult and quite taxing to continue with a consistent fictitious identity. It also makes the transfer to telephoning or meeting quite impossible. Most chatters will disguise one or two aspects of themselves in their online persona (weight or size, for instance) but do on the whole keep in line with reality.

Chatting may be an entertaining pastime for short breaks, just like computer games or TV broadcasts. In this case, no closer contact with the other chatters is sought. On the other hand, chatting can come a highly social activity. Some chatters are regular visitors to their chat rooms, as others may be regulars at a pub; they know members there personally and feel as if they belong to a chat community. They may at times take voluntary responsibility for managing the chat room, perhaps designing a homepage for it or organizing meetings and parties in real life for the other chatters.

A chat room's clientele will generally be composed of regulars, and, on the periphery, occasional visitors plus the people known as *lurkers*. The latter are people who visit online forums or chat rooms and merely observe what is going on without expressing themselves actively. Each chat room functions in accordance with its own rules. They may be written rules in the form of *chatiquette*. Chatiquette prescribes what behavior is frowned upon and what the sanctions are. The options for sanctions and punishment in chat rooms are technical (when people are mechanically excluded, e.g.) or social (when other chat participants express criticism or derision).

There are group dynamics in operation in chat room populations just as in face-to-face groups; there are outsiders, leaders, popular members, troublemakers, and clowns. There is the possibility for conflicts and arguments but also for a strong sense of solidarity. Chat rooms frequented by a relatively small number of people who know each other well tend to make it difficult for newcomers to integrate into the community. Large chat rooms with dozens or even hundreds of simultaneous participants tend to be confusing and feel anonymous. In this case, chatters often retreat for dialogue or small-group conversation into a private chat area, often called a *separée,* where they will not be disturbed and where they may engage in cybersex.

For children and adolescents, chat rooms constitute new opportunities for entertainment and contact which may well encourage them in their development. However, it is wise for children and adolescents to be made aware of the risks inherent in chatting and the precautions they can take. There are many *teen chats* and chat rooms for children that are subject to special rules and are under constant supervision so that misbehavior can be tackled immediately.

LINGUISTIC PROCESSES IN CHAT ROOMS

Because chatting as written conversation requires typing and reading at lightning speed, it is understandable that

a specialized chat language has become necessary. This language, closely observed, reveals a great deal of linguistic variety.

Abbreviations are the first means by which chat language speeds up the writing. Some well-known examples are LOL (laughing out loud), ROFL (rolling on the floor laughing), and IMHO (in my humble opinion). In addition, the variety of written language, consciously used, is very informal. People employ colloquial expressions, dialect, slang, and so on, to express a sense of belonging or absence of formality. There are also many ways of expressing emotions and nonverbal language: "smilies" such as :-) or :-(and words for actions or sounds such as *sigh*, *grin*, *smile*, *cuddle*, *yawn*, together with an abundance of exclamation marks (Hi!!!!!!!). Although there is some criticism that chat ruins language, linguists actually note the creativity involved, which includes linguistic humor and fun and games. Chat competence cannot exist without social competence or, indeed, without a certain amount of special linguistic competence, for chatting works best with humor and clever repartee.

CHILD-CENTERED VS. MEDIA-CENTERED PERSPECTIVES

Researchers and writers in media studies and media education debate the effects of experience with media (e.g., television, movies, video games, the Internet) on children and adolescents. The two major approaches in this debate are sometimes called *media-centered perspectives*, which focus on the influence of media on children and adolescents, and *child-centered perspectives*, which focus on their interaction with media.

Research and writing from a media-centered perspective are characterized by the belief that the influence of the media on children and adolescents is primarily negative and that children and adolescents are passive recipients of media messages, somewhat akin to empty vessels filled and shaped by media messages or even brainwashed by the media. Media-centered perspectives have a longer history than child-centered perspectives and emerge from media critiques from a wide range of political, cultural and religious views. Some media critics argue that the media influence children and adolescents with morally questionable ideas and images, lead to the degradation of traditional values, or give rise to violence. Other media

critiques argue from this perspective that the media influence children with unacceptable messages and images that give rise to rampant consumerism, violence, negative self-images, and discriminatory representations of humans.

Child-centered perspectives, also commonly called *audience response perspectives*, arose in response to what some researchers and writers saw as an overly simplistic model of audience effect in media-centered perspectives. These critiques contend that the media-centered approach fails to take into account the individual and social interactions of children and adolescents with the media, which mediate, limit, and shape the viewer's reception of media messages. They argue that children and adolescents are active, selective, and critical consumers of media. According to the child-centered perspective, the meanings children make of media messages are complex and unstable; they are negotiated in relation to viewers' identities (racial, gender, and social class, to name a few), their communities, their peer cultures, and other factors of their contexts. From this perspective, meaning is made in an active exchange between the media and the child or adolescent, and therefore there are many possible messages or meanings that children might make of any single media event.

Child-centered writers argue that media are an authentic part of children and adolescents' cultures and that this perspective is more democratic and more responsive to children and adolescents' interests, desires, and goals. However, media-centered critics respond by arguing that proponents of the child-centered approach are naïve about the power of the media to shape children's desires in ways that are inauthentic or objectionable. The argument between these two perspectives may be said to come down to different perspectives on the power of the media to persuade or influence child and adolescent consumers of media and on what counts as worthwhile culture.

Each perspective brings with it different educational responses. From a media-centered perspective, teaching about the media is seen as a means of providing children and adolescents with tools of analysis that will make them less vulnerable to and more critical of media influence. From a child-centered perspective, media education classrooms may be a place to investigate students' investments and pleasures related to media. In such approaches, critique of the media proceeds by highlighting the ambivalences and contradictions that students feel toward the media—for example, when a student enjoys a song, magazine, or movie but also understands it to present negative messages about a facet of the student's identity. In both kinds of classrooms, students may be made aware of or may make others aware of outlets for alternative media messages.

CHILDHOOD, MEDIA PORTRAYALS OF

Few studies devote themselves exclusively to media portrayals of childhood, and few of those look at a variety of media. The relative lack of research on the image of children and teens in the media suggests that this is an area ripe for study. However, some studies have examined changes in portrayals of television families over time and gender differences in television depictions of youth. Other research has analyzed the roles of youth who are featured as central characters in films. However, future research needs to examine the roles that younger people play in a variety of media.

Susannah Stern, who studied film images of teens, wrote in 2005 that no previous studies had systematically documented patterns in the portrayal of teens in film. She suggests that the lack of research on media images of youth is due to scholars' attention to the impact of media on youth rather than to what adults can learn about young people from the media. There are, however, a few examinations of the roles of children in television families. Children are a stable feature, particularly in situation comedies, and frequently they are at the center of the action on those programs.

TELEVISION FAMILIES

William Douglas and Beth Olson conducted an extensive content analysis of television families from 1950 to 1990 and found that the experience of children in these families has deteriorated. Their lives in the more recent decades were more conflicted, less cohesive, and less manageable than in previous decades. Relationships among siblings were more hostile and less cohesive as well. Along these lines, in 1991 Mary Larson compared sibling interaction on 1950s sitcoms with that on 1980s sitcoms. She compared *Father Knows Best, Leave It to Beaver,* and *Ozzie and Harriet* with *The Cosby Show, Family Ties,* and *Growing Pains.* She found that interactions were more positive—that is, included supportive or positive statements or nonhostile teasing—in the 1950s but were more important and more central to the story in the 1980s.

P. A. Cantor's in-depth look at *The Simpsons,* an animated family comedy show that first aired in 1989, examines how the Simpson children and their lives are portrayed. The Simpsons live in small-town America, the children attend a neighborhood school, and the whole family goes to church regularly. One of the three children is a baby; the other two are older and have distinct personalities. Bart is portrayed somewhat stereotypically in that he is always in trouble, "troublemaker" being a trait more often assigned to boys than to girls. He is rebellious and has no respect for authority, particularly educational authority. Lisa is an overachiever in school, a feminist, a vegetarian, and an environmentalist. She is also an activist who is not afraid to take on the entire town when outraged about something. In contrast to both Bart and Lisa, the two neighbor boys are well behaved and obedient.

GENDER DIFFERENCES

Two studies by Kate Peirce looked more specifically at television's child characters themselves, analyzing the attributes and activities of the characters to see where there were gender differences. Significant differences were found with the bipolar adjectives active–inactive, aggressive–passive, rational–irrational, and unhappy–happy. Boys were associated with the adjectives *active, aggressive, rational,* and *unhappy.* Boys and girls also participated in stereotypically male and female activities. Girls played dress-up, helped in the kitchen, talked on the phone, and played with dolls. Boys participated in sports and other outdoor activities and were more likely than the females to make mischief and get into trouble. A similar analysis some years later found fewer divisions between the sexes. Girls were considered more fashionable and emotional than boys, but all were considered smart, active, somewhat aggressive, attractive, happy, skinny, popular, and somewhat strong. There were no significant differences in the gender of those who participated in activities considered male or neutral, but few males participated in activities considered female. Activities considered masculine included rescuing people; breaking and entering and other illegal or mischievous acts; and playing video games, pool, and poker. Female activities included shopping, talking to friends, taking ballet lessons, and putting away groceries.

TEENAGERS IN FILMS

In her study of popular films and the image of teenagers, Stern looked at films from 1999 to 2001 that featured one or more teenagers as central characters. She wanted to examine the types of behaviors the characters engaged in, what motivations were expressed, to what extent their parents were depicted, and what sort of relationship parents had with their children. She found that most characters (86.3%) were white; among the white characters, genders were equally represented, but nonwhite characters were more likely to be male. The most common activities for the characters were hanging out, socializing at school, and making out. These were followed by grooming, being victimized by violence, and committing violence. More socially positive activities, such as caring for family or volunteering, were rarely shown. The primary motivation for the characters was a romantic relationship. Their parents were rarely shown in the films, and only 15% of the characters were depicted as living in residence with two parents. Stern believes the problems with such depictions of young people are that (1) the popular behaviors shown were self-serving, pleasure-seeking, and violent, whereas the actual teen crime rate is at its lowest in 25 years; (2) the absence of teens as workers, volunteers, and caregivers may contribute to adults' ideas that teens are lazy and irresponsible; (3) parents were depicted as only mildly competent and in touch; and (4) racial stereotyping was present; nonwhites were significantly more likely to commit violence.

The few studies about coverage of youth in the news found that the most common stories deal with youth as victims or perpetrators of crime.

CHILD PORNOGRAPHY

Sex is the number one topic searched for on the Internet. Americans spend $10 billion each year on pornographic materials such as magazines and videos—as much as they spend to attend sporting events and movies or to purchase music. Few areas of sexual behavior arouse as much condemnation as child sexual abuse, and child pornography (despite lack of a consensus definition) is often considered the epitome of sexual abuse. The U.S. Customs Service estimates that more than 100,000 websites offer child pornography worldwide, more than half of which have originated in the United States. Such websites have made such pornographic materials easier to disseminate and to access than ever before, and the prevelance and distribution of child pornography has become a national concern.

In the United States, child pornography is prohibited under both federal and state laws, with some state laws including more or less restrictive definitions compared with federal law. Under federal law, *child pornography* is defined as visual depiction of minors (under the age of 18) engaged in a sex act such as intercourse, oral sex, or masturbation as well as the overt depictions of genitals. It has been suggested by academics and others that the consumption of child pornography may cause pedophilia and lower the threshold of a person's willingness to engage in sex with a child through the process of desenitization. On the other hand, it is argued that these materials may potentially give pedophiles a sexual outlet, thereby lowering sexual frustration and the risk of committing abuse. Research in this area is inconclusive.

THE EXTENT AND DISTRIBUTION OF CHILD PORNOGRAPHY

Reports of suspected child pornography climbed 39% in 2004, according to the National Center for Missing and Exploited Children, which collects tips about the problem both online and by telephone. The organization's CyberTipline logged more than 100,000 reports of possession, creation, or distribution of pornography featuring children in 2004, the seventh consecutive year that such incidents increased since the 24-hour hotline was established in 1998. On a positive note, indecent images of children posted on websites and newsgroups over a 4-year period from 1998 to 2002 were sampled, and a significant decline in the number of such images posted on the Internet was observed, likely due to the pressure of groups opposed to the distribution of such exploitative material.

Child pornography on the Internet is available in many different formats, ranging from pictures, anime cartoons, and video to sound files and stories. Most pornographic material is distributed via email, newsgroups, or Web pages. Child pornography is also distributed during conversations in chat rooms and through interactive home pages. The Internet provides offenders with a large degree of security and anonymity, resulting in the rapid increase in the distribution of child pornography online. It is likely that the anonymity and convenience provided through online interactions has contributed to an increasing population

of child pornography consumers who did not actively seek out such material through the more traditional media due to lack of access and fear of being caught.

A study conducted in 2003 by the Crimes Against Children Research Center at the University of New Hampshire examined 2,577 arrests for online juvenile victimization and found that more than two thirds of those who sexually violated juveniles possessed child pornography, and 36% of the arrests related exclusively to trading Internet child pornography. Child pornography as an industry, which is illegal worldwide, continues to grow as well.

CHARACTERISTICS OF PORNOGRAPHY CONSUMERS

An investigation by Ian Munro and Catharine Munro states that little is known about child pornography consumers. Little empirical data exist on the characteristics and motivating factors of individuals who seek out child pornography. Research suggests that such individuals are generally between the ages 25 and 50 with no prior criminal background. Further, individuals who have accessed child pornography tend to be better educated and of higher intelligence and are more likely to be employed and to be in relationships than those who commit hands-on sexual offenses against children.

In a research effort conducted by Ethel Quayle and Max Taylor to better understand the motivation to seek out child pornography, 13 men convicted of downloading child pornography from the Internet were interviewed, with an emphasis on how these men talked about the role of child pornography in their lives. Some of the themes that emerged from these accounts were sexual arousal, along with child pornography as collectibles, to facilitate social relationships, and as a way of avoiding real life. This research again illustrates the important role of the Internet in increasing sexual arousal to child pornography; it also highlights individual differences in whether this serves as a substitute or as a blueprint for contact offenses of pedophilia.

GOVERNMENTAL RESPONSES

In response to the growing number of incidents involving child pornography, the Federal Bureau of Investigation (FBI) has launched a task force to deal exclusively with the issues surrounding child pornography. The FBI pursued approximately 700 cases of child pornography in 1998, and by 2001 the taskforce was investigating more than 2,800 cases.

On June 23, 2003, the U.S. Supreme Court upheld the constitutionality of the Children's Internet Protection Act (CIPA). Ratified in December 2000, the CIPA requires schools and libraries receiving federal funds for Internet access to block or filter access to visual depictions that are obscene or feature child pornography and to material that could be deemed harmful to minors.

State legislators also have begun to take action to prevent the distribution of child pornography. The Pennsylvania legislature passed a law requiring Internet service providers to block access to websites containing child pornography. The American Civil Liberties Union (ACLU) and the Center for Democracy and Technology (CDT) challenged the law on the grounds that it was unconstitutional under the First Amendment, alleging that the law requires blocking access to many websites that have nothing to do with child pornography. A federal judge agreed with the ACLU and the CDT and overturned the Pennsylvania law on the grounds that the tools for blocking child pornography sites also cause "massive suppression" of constitutionally protected speech.

CHILDREN NOW

Children Now is a national organization dedicated to making children's needs a top public policy priority. For more than 12 years, the Children and the Media Program at Children Now has worked to ensure that all children have access to a media environment that supports their healthy cognitive, social, and emotional development. As a leading public policy player in the field of children and the media, Children Now has played an important role in major policy issues that range from the V-chip and the television ratings system to the Children's Television Act and digital television. Children Now also has testified before the Federal Communications Commission and the Senate Commerce Committee on topics such as the impact of media consolidation on children's programming and how the TV ratings system could better serve families. Its work is supported through foundation grants (90%) and individual donors (10%).

Children Now recognizes that the media industry, parents and caregivers, federal regulators, and policymakers each have a role to play in creating a healthy media environment for children. To raise awareness and inspire action from each of these groups, Children Now conducts groundbreaking, timely research on media issues affecting children.

Research conducted by Children Now includes "A Different World," which studied the messages about racial and gender diversity that are sent to boys and girls across a range of media and the impacts those messages have on young viewers; "Big Media, Little Kids," which revealed the harmful effects of media consolidation on children's programming; and "Fair Play? Violence, Race, and Gender in Video Games," which found that an overwhelming majority of popular games contained significant amounts of violence and that the ratings for these games often did not acknowledge the violent content.

Children Now uses this research to educate each group of stakeholders and to provide resources and tools to enable them to make programming, viewing, and policy decisions that support children's healthy development. This strategy has enabled Children Now to win significant victories for children. Its research on the importance of racial and gender diversity to children and subsequent outreach to media industry leaders resulted in creation of Dora the Explorer, the first Latina, bilingual heroine in children's programming, and one of the most popular children's television characters in history.

Children Now's research on the detrimental effects of media consolidation on the quantity and accessibility of children's programming prompted the Federal Communications Commission to include a stipulation in their 2003 media ownership ruling protecting children from the likely harmful outcomes of media deregulation. In 2004, Children Now won a landmark victory for children and families when the Federal Communications Commission unanimously approved its recommendations regarding new rules for children's television. The new rules ensure that children have access to more educational programming and that parents have more information about how to find that programming as television transitions from an analog to a digital format.

CHILDREN'S ADVERTISING REVIEW UNIT (CARU)

The Children's Advertising Review Unit (CARU) was founded in 1974 by the National Advertising Review Committee (NARC) to promote responsible children's advertising. NARC is a strategic alliance of advertising industry organizations, including the American Association of Advertising Agencies (AAAA), the American Advertising Federation (AAF), the Association of National Advertisers (ANA), and the Council of Better Business Bureaus (CBBB). NARC has two self-regulatory investigative arms: the National Advertising Division (NAD) and CARU. NAD self-regulates national advertising, and CARU self-regulates national advertising to children aged 12 and younger in all media (for the Internet, advertising to children under 13). CARU is considered a very powerful self-regulatory program, as it has formulated and successfully implemented its advertising principles and guidelines to promote responsible advertising to children over the past three decades.

CARU'S ADVERTISING REVIEW

CARU is responsible for receiving or initiating reviews of advertising; evaluating, investigating, and analyzing advertising; holding negotiations with advertisers; and resolving complaints or questions involving the truth or accuracy of national advertising, or its consistency with CARU's *Self-Regulatory Guidelines for Children's Advertising.* Any person or legal entity, including CARU as part of its monitoring responsibility procedures, may submit any complaint regarding national advertising directed to children. If an advertisement is found to be misleading, inaccurate, or inconsistent with CARU guidelines, CARU seeks changes through negotiation with the advertiser and through the voluntary cooperation of the advertiser. If the advertiser elects not to participate in the self-regulatory process or refuses to cooperate, CARU prepares a review of the facts and submits it to the appropriate federal or state law enforcement agency.

CARU'S REVIEW PRINCIPLES AND GUIDELINES

In 1975, CARU formulated seven basic principles that embody the philosophy upon which CARU's mandate is based. These seven principles determine the scope of CARU's review of advertising and provide a basis for CARU's guidelines, many of which impose limitations on advertising practices beyond those imposed by any law or regulation. Whereas the principles broadly state the responsibilities of advertisers, the guidelines are specific and comprehensive and indicate what advertisers should or should not do. According to the guidelines, for example, children should not be urged to ask parents or others to buy products in an advertisement (e.g., "Tell your mom you want this"). In sweepstakes advertisements, the likelihood of winning should be clearly disclosed in language understandable to children (e.g., "Many will enter, a few will win"). The guidelines are broad enough and detailed enough to cover many product categories and advertising presentations directed to children. When no specific guideline addresses the issues of concern in an advertisement, CARU will apply the principles to the evaluation of the advertising.

CHILDREN'S INTERNET PROTECTION ACT OF 2000 (CIPA)

The Children's Internet Protection Act (CIPA) was enacted by Congress in 2000. The Federal Communications Commission (FCC) is responsible for its implementation. CIPA compels public schools and libraries receiving federal funding for Internet access to install a "technology protection measure" on each computer that connects to the Internet; they are also required to have a formal Internet safety policy.

The motivation for CIPA is to block children from accessing inappropriate sexual content online. Specifically, the law requires visual depictions that are obscene, contain child pornography, or are harmful to minors to be filtered on computers in public school and libraries. Textual content is not covered by CIPA. Obscenity and child pornography are not protected by the First Amendment in any medium, but the provision of blocking material that is harmful to minors is new. The law provides a definition of what material is "harmful to minors": depictions of nudity, sex, or excretion that, when taken as a whole, are presented in a "patently offensive" way and are determined to lack "serious literary, artistic, political, or scientific value as to minors." Critics of the law charge that this definition is still too broad and subject to inconsistent application.

Most schools and libraries fulfill the obligation for a technology protection measure by installing a software program capable of filtering access to offending content. The law makes clear, though, that authorized personnel must be willing and able to disable the filter program when requested by an adult. Critics of the filter requirement argue that existing filters are a form of censorship that blocks a vast amount of valuable information along with pornography. Supporters of CIPA, however, argue that excessive blocking presents minimal danger when compared to the risks of allowing children unfettered access to the Internet. Another argument in support of filters is the protection of libraries and librarians. The presence of filters

is seen as a preventative action against potential lawsuits regarding children's access to inappropriate materials.

CIPA advocates also point out that public libraries and schools can opt out of the requirement by foregoing public funding for technology updates. In *U.S. v. American Library Association,* the U.S. Supreme Court agreed, ruling CIPA constitutional because a school or library can opt out. Opponents counter that libraries in areas of poverty cannot provide Internet access unless they receive government support. Fewer people in these areas have home Internet access and therefore rely on public libraries for access.

The Internet safety policies required by CIPA address a broader range of computer-related issues. These policies must encompass access to inappropriate materials on the Internet, but they also must have provisions for handling security issues, for protecting children's privacy, and for dealing with children's use of computers for illegal activity (e.g., hacking into another computer system).

CHILDREN'S ONLINE PRIVACY PROTECTION ACT OF 1998 (COPPA)

The Children's Online Privacy Protection Act of 1998 (COPPA) regulates the collection and use of children's personal information by website operators. Passed by Congress, COPPA assigns the tasks of issuing specific rules and handling enforcement to the Federal Trade Commission (FTC). The law applies to commercial websites aimed at children under the age of 13 and to general-audience websites that have "actual knowledge" that they are collecting personal information from children.

Operators of these sites must post comprehensive but clearly written privacy policies regarding their practices in handling children's personal information. They must also notify parents and (with a few exceptions) obtain verifiable parental consent before collecting the child's private information. Furthermore, parents must be given the option to allow the collection and use of their child's information by the website internally but deny the operator freedom to disclose the information to outside entities. Parents must also be able to review personal information provided by their child and correct or delete it. Parents must have the chance to prevent further collection or use of the child's information, and website operators are expected to take the steps necessary to safeguard the information they collect. Finally, COPPA bars operators from requiring children to disclose more personal information than is reasonably necessary to participate in the activity in question.

The FTC established a sliding scale approach to the level of parental consent that website operators must obtain. If a website operator is using the collected information for internal purposes, it can obtain parental consent via email. An initial notice is sent to the parent, and then some additional follow-up is required to confirm consent. If collected information is to be disclosed to third parties or made publicly available, then more reliable methods of consent are required. Acceptable measures are providing a form for parents to complete and mail or fax back to the operator, asking the parent to use a credit card in a transaction with the site, maintaining a toll-free number for parents to call, or allowing parental emails that have a digital signature.

No parental consent is required to collect a child's name and his or her parents' email address for purposes of providing notice and seeking parental consent. Also, website operators may use a child's email address once in response to a specific request from a child, as long as the email address is deleted afterwards. Email addresses may be collected to respond multiple times to a child's request (e.g., for an online newsletter) if, after the first reply to the child, parents are notified and given the choice to have their child's information deleted. Website operators are also allowed to collect name and email addresses when necessary to protect the safety of the child or the security of the site.

Critics of COPPA question the decision to apply safeguards only to children under 13, as individual children may require more or less adult supervision depending on their cognitive development. Also, some argue that the methods of collecting parental consent are too costly, too time consuming, and ineffective in

protecting personal information. First Amendment advocates are concerned that any personal identification requirements for accessing online content infringes on a person's right to communicate anonymously.

COPPA is distinct from the Children's Online Protection Act (COPA), another law passed in 1998. COPA dealt with protecting children from accessing inappropriate materials, such as pornography, on the Internet. COPA never went into effect, as its constitutionality was challenged, and the Court ruled that it violated the First Amendment.

CHILDREN'S TELEVISION ACT OF 1990 (CTA)

The Children's Television Act of 1990 (CTA) establishes limitations on advertising during children's programming. It also gives the Federal Communications Commission (FCC) a directive to consider broadcast licensees' service to children's educational and informational needs when reviewing applications for license renewal.

This legislation is designed to provide incentives for broadcast television licensees to better serve children's needs. As grounds for the CTA, Congress found that television's prosocial potential was not being fulfilled. It stated that children are an audience with special characteristics requiring unique programming standards and noted that there are financial disincentives for commercial broadcasters to air educational and informational programming for children.

The FCC is the administrative agency charged with implementing laws regarding electronic media. To implement the CTA, the FCC set specific limits on the amount of advertising that can air during children's programming. During the week, broadcasters are permitted to run 12 minutes worth of ads per hour. On the weekends, stations can run only 10 minutes of commercials per hour of children's programming. The FCC routinely audits children's programming to assess compliance with these limitations. Any licensee found to violate these rules is asked to review its programming more thoroughly and correct problems.

The requirement that the FCC review broadcasters' provision of educational and informational programming for children has been more challenging to implement. Initially, in a 1991 order the FCC indicated that broadcasters were expected to offer "some" educational programming for children each week. As they reviewed licenses for the next 3 years, this criterion was met if licensees could demonstrate they had aired at least one half-hour show per week that served children's needs. Because the regulations were so vague, the FCC later determined that the economic marketplace was still not providing sufficient incentives for production of this sort of programming. Additionally, broadcasters were citing as educational programs that the FCC deemed to be primarily serving entertainment needs, such as *America's Funniest Home Videos* and *Yogi Bear*.

In 1996, the FCC issued more specific guidelines for this portion of the CTA. They indicated that broadcasters would meet their obligation if they had 3 hours per week of shows "specifically designed" to educate or inform children. Such programming also must be regularly scheduled, must be at least 30 minutes in length, and air between the hours of 7 a.m. and 10 p.m. Furthermore, the program must be identified as educational and informational when it is broadcast, and it must be listed in the public inspection file each licensee maintains.

The group Action for Children's Television (ACT) was influential in lobbying for the CTA of 1990. Formed in 1968 by Peggy Charren, the passage of this legislation was the culmination of 22 years of advocacy on behalf of children's television.

CHILDREN'S TELEVISION CHARTER

The Children's Television Charter affirms the rights of children that are identified in the United Nations Convention on the Rights of the Child, as these relate to television programming for and about children. The charter was presented by advocates for children's television led by Anna Home, head of Children's Programmes, Television, BBC, to the First World Summit on Children and Television, held in Melbourne, Australia, in March 1995. It was revised and approved at the Prix Jeunesse Round Table in Munich, May 1995, and has been adopted in many countries around the world.

The charter took its lead from the United Nations Convention on the Rights of the Child (ratified by nearly all countries, though not by the United States), which asserts children's rights to freedom of expression through any medium of the child's choice (Article 13) and to mass media that disseminate information and material of social and cultural benefit to the child, with particular regard to the linguistic needs of minority and indigenous groups and to protection from material injurious to the child's well-being (Article 17). Thus, the Children's Television Charter asserts children's rights to receive quality programs; to see and express themselves, their culture, their language, and their life experiences through the media; and to have access to media that affirm their sense of self, community, and place.

Specifically, the charter states:

(1) Children should have programmes of high quality which are made specifically for them, and which do not exploit them. These programmes, in addition to entertaining, should allow children to develop physically, mentally and socially to their fullest potential;

(2) Children should hear, see and express themselves, their culture, their languages and their life experiences, through television programmes which affirm their sense of self, community and place;

(3) Children's programmes should promote an awareness and appreciation of other cultures in parallel with the child's own cultural background;

(4) Children's programmes should be wide-ranging in genre and content, but should not include gratuitous scenes of violence and sex;

(5) Children's programmes should be aired in regular slots at times when children are available to view, and/or distributed via other widely accessible media or technologies;

(6) Sufficient funds must be made available to make these programmes to the highest possible standards; and

(7) Governments, production, distribution and funding organisations should recognise both the importance and vulnerability of indigenous children's television, and take steps to support and protect it.

The charter specifies a set of benchmark principles to help protect good-quality children's television. The charter was subsequently extended to include all electronic media at the Third World Summit in Thessaloniki in 2001, and it is now variously named, in different countries, the Children's Charter on Media, or Electronic Media, or Television. The charter has stimulated a series of international meetings in which senior broadcasters, media professionals, and researchers have met periodically since 1995 to develop a series of action points for implementing the charter. At the Second World Summit in London, children produced their own charter as well. However, although widely supported, it seems that, as yet, there have been few national and no international attempts to evaluate the success of the charter in altering the media landscape for children around the world.

CHILDREN'S TELEVISION WORKSHOP

See SESAME WORKSHOP

CHINA, MEDIA USE IN

In the past 25 years, children's media in China have seen a great increase in the amount of content produced by both domestic and foreign media institutions. This entry focuses on the growth and transformation of the Chinese children's media, ranging from TV programs, movies, and cartoons to music, advertisements, and the Internet. Also discussed are several sociopolitical factors—the one-child policy, parental control, government's appropriation of the media for ideological and educational purposes—that influence children's media interactions. Finally, this entry highlights contemporary Chinese children's interpretive competency regarding media messages and their creative adaptation of various genres and content to their own tastes and interests.

The history of children's media in modern China can be traced back to 1874, when the first children's newspaper in China, *Xiaohai yuebao* (*The Child's Paper*), was published in Guangzhou. Then, a series of other children's publications followed during the Republican era (1912–1949), including *Shaonian zazhi* (*Youth Magazine), Ertong shijie* (*Children's World*), and *Xiao pengyou* (*Little Friends*). Researchers show that these early print media intended to foster brave, independent, and hardworking children who were equipped with critical thinking and democratic ideas. After 1949, many new books and newspapers for children emerged in China, including *Hao haizi* (*Good Children*), *Hong haizi* (*Red Children*), *Hong xiaobing* (*Little Red Guard*), and *Xin shaonian* (*New Youth*). Operating as part of a communist ideological system, these print materials aimed at cultivating communist allegiance among children and transforming them into loyal "successors of the communist cause."

As China entered its reformist era (1979–present) and opened its door to the rest of the world, children's media proliferated. A recent study shows that, in addition to newspapers, contemporary Chinese children are catered to by television, films, cartoons, magazines, and the Internet. Statistics also indicate that today's Chinese children prefer visual and audio materials to books and magazines. An average Chinese child spends 2.22 hours a day watching television and 3.53 hours a week using the Internet for music, movies, games, and chat-room socializing. In regard to media production, in 2000 there were already about 640 television stations broadcasting to children. CCTV (Chinese Central Television) alone offered 8 hours of programming per day. In 2003, CCTV debuted its children's channel, and since then it has provided 18 hours of children's programming a day. If the time that CCTV devotes to family films every day on its movie channel is included, the amount of children's programming is even higher. Moreover, during the past two decades, through its Children's Film Studio, the Chinese government has produced 90 children's films and has required the studio to keep producing at a rate of at least five movies per year. Meanwhile, China's domestic cartoon industry, although seriously threatened by Japanese and American imports, is trying to recapture Chinese children's animated imagination by fusing cutting-edge technology and traditional Chinese cultural and aesthetic values.

CONTENT OF TV, FILMS, CARTOONS, AND MUSIC

Although the quantity of children's media has increased dramatically in China, the content of these domestically produced media has been criticized by both scholars and media workers as out of touch with children. One senior scholar of children's films once pointed out that Chinese filmmakers usually do not respect the creativity of their audiences. Hence, their movies often express ideas that bear little connection to children's imagination and interests. Meanwhile, domestic children's programs still function for the state's education of children to become obedient and loyal citizens. Scholars argue that these programs have a clear moral, ideological orientation, emphasizing patriotism, social responsibility, self-fulfillment, filial piety, good manners, and the importance of collectivism and education. For instance, as one scholar documented, children in Chinese domestic media are often portrayed as agents and repositories of pride, cohesion, hope, and concern, who usually display their anger at aggression toward China and their enthusiasm for national unification. Scholars further show that Chinese children today are less and less comfortable with this pupil-teacher relationship with media. They actively interpret and interact with media content. Such an interaction, discussed in detail later, is on some level fueled by alternative imaginations enabled by the children's encounters with transnational media materials.

Accompanying the domestic proliferation of children's media is the increased accessibility of

foreign programs and materials, including Disney's *Mulan*, Japan's *Pokémon*, and Britain's *Harry Potter* series. Chinese children display incredible passion for and competence of consumption of these foreign images and stories. As a result, in order to enhance popularity, even state-sponsored publications feel the need to feature Mickey Mouse, American pop icons, and Teletubbies. Meanwhile, children's passion for foreign materials generates concerns and criticisms among educators and parents. As previous studies show, parents and teachers often criticize foreign media for instilling materialist values into children, turning them into consumers who are emotionally cold, unwilling to act unselfishly, and indifferent to the values that their parents and teachers have held central to their identities. They also have concerns over the body images and the more explicit sexual messages in American and Japanese programs, such as the images of the heroes and heroines in Japanese cartoons. Japanese cartoon characters often have children's faces but adult bodies, which, according to Chinese parents and teachers, offer a confusing self-image to young audiences. These cartoons are also criticized for perpetuating gender stereotypes, with males portrayed as more aggressive, rougher, sloppier, and stronger, and females more beautiful and more feminine.

Chinese youth music also bears the influence of Western music, such as heavy metal, rock and roll, and hip hop, although, as reports show, MTV and Channel V—Murdoch's made-for-Asia competitor to MTV—can broadcast to only a few major cities in China. Journalists write that Chinese young people started to embrace rock and roll and heavy metal in the late 1980s and the early 1990s. This music is popular among young people not so much because of the quality of the music itself but because of the social attitudes toward this type of music—unapproved and feared by parents—and because listening to it is seen as rebellious. The pioneering Chinese rock bands that young people identified as their idols in the early 1990s include *Tang Dynasty* and *Hei Bao* (*Black Panther*), whose music largely offered an emotional and social outlet for their audiences.

As more recent reports show, hip hop is winning more and more fans in Chinese metropolitan cities such as Shanghai. Young fans not only enjoy the music but also pick up its fashion, dressing as if they have just stepped straight off a New York street. For these young audience members, hip hop music and lifestyle symbolize freedom, self-expression, and life expansion.

Given the popularity of hip hop among Chinese youth, even the dominant communist ideology in China has decided to add a hip-hop spin to its old doctrines in order to sustain its influence among young people. Journalists report that in 2003 the China Record Company released an album in which Mao Ze-Dong's theories were made into rap songs. The company sold 30,000 recorded tapes and CDs in a month. This case, showing how rap, an African American, inner-city cultural form, can be appropriated in a Chinese context to carry on communist legacies, functions as a counterargument to the theory that gloalization is essentially a process of Americanization.

If rock and roll and hip hop are radically changing Chinese youth's music, some softer popular songs from Taiwan and Hong Kong—places of more liberal atmosphere—are gradually making their way into a territory that so far has been occupied solely by communist revolutionary songs: Chinese children's music classes. Reports show that, by 2005, music classes in Shanghai could teach students some "inspirational" pop songs. Although these songs were preapproved by the government for classroom use, they demonstrate the government's willingness to cater to the tastes of young people, who have long been fed up with singing only monotonous revolutionary songs.

ADVERTISEMENTS

In addition to TV programs, movies, cartoons, newspapers, and music, another important medium that targets cultural content to children is advertising. The Chinese government has enforced the one-child-per-family policy since 1979. As a result, a typical family configuration in China today is one child, two parents, and four grandparents—which, according to researchers, has significantly changed the power dynamic within the family. These only children are brought up as little emperors and empresses. Because their parents and grandparents often hold little authority over them, these children can get practically anything they want. Meanwhile, parents and grandparents do not hesitate to invest in their children's intellectual and physical growth. As scholars have documented, Chinese children are given more than $3 billion annually to spend as they wish; more important, they decide 65% of their parents' spending, probably the highest rate of influence in the world. As a result, more and more domestic and international businesses are starting to focus their campaigns on Chinese

children. Major American businesses in China include McDonald's, Disney, KFC, Nike, Adidas, and M&M.

In terms of quantity, previous studies show that, through CCTV Channel 1 alone, domestic and international advertising is able to reach 8,330,000 Chinese children ages 4 to 14 for 3 evening hours (6 p.m. to 9 p.m.). A child who spends 3 hours per day watching television may encounter 16,000 advertisements during the year.

In terms of content, studies show that the content of commercials in China reflects China's traditional cultural values and its current socioeconomic environment. The marketed traditional values include collectivism, avoidance of uncertainty and confrontation, face saving, and masculine authority, to name a few. They often coexist with Western cultures and lifestyles in both foreign and domestic commercials, partly because of foreign businesses' localized marketing strategies and partly because of the entry of Western cultures into China's own popular cultural sphere. For instance, some children's commercials manage to emphasize universal acceptance or popularity, echoing the traditional Chinese value of collectivism, without devaluing the unique appeal of their products, which is in line with the Western value of individualism.

Also, the content of both domestic and foreign commercials is subject to the regulation by the Chinese government through its Advertising Censorship Standards. Scholars argue that these standards censor commercials to guarantee cultivation of children's good behaviors and values. For instance, the standards mandate that children shown in commercials should function as models for the child audience—for example, they should not put pressure on their parents or disrespect their elders and other people. Yet, scholars do criticize the government, arguing that, although government censorship has greatly shaped the content of children's commercials, it has not adequately protected children from dishonest and misleading information in advertising.

Based on the foregoing information on the quantity and the content of both domestic and international commercials, it is safe to say that advertising has become the most popular medium used by businesses to communicate with Chinese children and to cultivate in them commercially desirable lifestyles. Considering all genres of children's media, we discover in them the continuing theme of fostering responsible citizenship as well as a broad appeal to children as consumers.

THE IMPACT OF PUBLIC POLICY AND PARENTAL CONTROL

As mentioned earlier, China's one-child policy has greatly changed the structure of Chinese family and the power dynamic within it. At the same time, scholars find that the policy has on some level strengthened the connection between Chinese children and the media, particularly television and the Internet. As lone children of the Chinese family, both parents of which usually work outside the home, they have grown up with the company of television in the absence of siblings. For them, television is the fourth audiovisual member of the family, playing a more important role than their parents in their socialization.

Another important social factor that impinges on children's interaction with media is parental control. Studies show that the flip side of lone children's increased power in the Chinese family is increased attention to and heightened expectations of them on the part of their parents and grandparents. As the school system in China grows more and more competitive, parents put more and more pressure on their children to excel in school. In some extreme cases, parents treat their children as the only bearer of their hope, whose performance at school brings either honor or shame to the family. As a result, parental control over the time and the content of their children's interaction with media has become a common practice in China. Chinese parents share a fear that too much time spent with media will cause poor school performance and that inappropriate media content, such as sex, will erode their children's moral integrity.

As research shows, 98% of Chinese parents exercise some control over the content of their children's television viewing and the amount of time they watch. The level of control ranges from persuasion to regulation or coercion. For example, the control of television includes switching channels, promoting certain programs that the parents regard as educational and informative, and prohibiting those they perceive as showing inappropriate content, such as love stories with sexual innuendos. Also, Chinese parents are concerned about the moral behaviors in commercials, and they tell researchers that they will exert more control over their children's exposure to advertising. As more and more media novelties—such as hotlines, chat rooms, the World Wide Web, and computer games—take the center stage in Chinese children's mediated lives, and as the Chinese government becomes less able to regulate

these new technologies, Chinese parents, who have been most keen on transforming the small screen into an instrument of education and discipline, find their power of control constantly threatened.

CHILDREN'S INTERACTION WITH MEDIA

Studies suggest that, contrary to their stereotypical image as introverted and obedient, studies suggest that many Chinese children have developed their own creative modes of media consumption. For instance, scholars show that parental control over viewing time and content often encounters underground resistance, as some children go to schoolmates' homes where the control is less tight to view favorite shows. These children's slogan, documented by one researcher, is, "You have your policy, I have my expediency."

Many Chinese children do believe in the importance of good school performance and display a level of self-regulation regarding their media consumption, but nevertheless they are quite cynical about their parents' instrumental use of the media. They avoid some ideology-loaded domestic programs and actively seek out imported content, such as Japanese cartoons, where their imagination can fly and where their relation to the characters is more equal than that of pupil and teacher.

Regarding the state's objective to produce patriotic, responsible, obedient citizens, Chinese children also display their negotiations. Research shows that Chinese children, especially those in developed urban areas, are growing into internationalized media consumers who have the ability to reconcile the tension between local traditional cultural values and the noncognate cultural challenges coming from international media. They negotiate a common ground for national loyalty, aesthetic taste, and brand awareness. They are local loyal citizens, but at the same time they have a taste for international media images and characters such as Mickey Mouse and Harry Potter. Hence, to recapture the interests of these active young media consumers whose horizons have already expanded into an international cultural arena, the Chinese media industry must clearly package together local content and international genres, modes, and tastes.

Chinese children also appropriate diverse media content for their own interests. A study shows that Chinese children use the Internet to make connections, to educate themselves on interpersonal relationships, and to share their youth cultures, which are informed by both domestic and international media materials. In this sense, the creative communication of these Chinese children on the Internet is beyond the sphere of control by their parents and the Chinese government.

Finally, Chinese children's active engagement with advertising is also worth our recognition. Although they are often the first within their families to learn of new products from the mass media, studies show that they are not totally susceptible to advertising appeals. As they grow up, their mistrust of advertising also grows. They ask for their parents' opinions, draw from their own consumer experiences, or even check the products at the stores to see if the commercials are true.

Given Chinese children's interpretive competency in relation to media messages and their creative appropriation of various media genres and content in their daily lives, scholars argue that films, cartoons, TV programs, Internet websites, and commercials must seriously consider these children's media use patterns and internationalized tastes in order to speak to their young minds and hence succeed as spiritual and commercial messengers.

CHOICE IN MEDIA USE

Children and adolescents are selective in their media use, just as adults are. Media exposure always involves choices because there is far more content available than can be consumed. However, these choices show different patterns during childhood and puberty compared to adults' media use, and, moreover, these patterns change greatly during the early years. Children's and adolescents' choices in media use are of particular interest because they reflect how these young people use media to self-socialize. As they look for role models for their orientations, a vast amount of media content is readily available. Not only does identity formation occur in these early years; entertainment preferences as well are said to emerge through early experiences (Zillmann & Bryant, 1985).

PRECONDITIONS OF SELECTIVE MEDIA USE

With regard to media channels, many children may learn to use the media independently and selectively through audio tapes. At least in industrialized countries such as the United States and Germany, cassette and CD players are the most common media equipment in children's rooms, even for children 6 years old or younger. Although their use of other screen media is more frequent, it is likely that preschoolers have only limited influence on the choice of content, because they are reported typically to watch television or use the computer together with others, mostly adults. Nonetheless, toddlers and preschoolers play a very active role in the media use process—they ask for and help themselves to the media content they prefer. According to a large media use study of children age 6 and under conducted by Rideout and colleagues in 2003, these youngsters exert choices by turning on the TV by themselves (77%), asking for particular shows (67%), using the remote to change channels (62%), asking for videos or DVDs (71%), putting in music tapes or CDs (36%), using the computer by themselves (33%), and loading CD-ROMs (23%); and a few even ask for specific websites while using the Web (12%).

The situation is different for children older than 8 years because the majority of them have TV sets in their own rooms and thus may often have little supervision during television use. Although research in the 1980s found that music listening gained importance during adolescence because teens wish to select and use media by themselves without other family members and could do so with audio media, this may no longer apply. Today, older children and teenagers between 8 and 18 years often have not only tape or CD players (86%) or radios (84%) in their own rooms but also TV sets (68%). Hence, they typically have many choices of content, often further broadened through VCRs, DVD players, and premium TV channels. In addition, half these older children and teenagers have their own electronic gaming devices in their bedrooms, often computers, sometimes with Internet access. Thus, teenagers are certainly no longer restricted to auditory media when they want to choose from media content by themselves. They often can select content at their will when other family members are not present. However, technical devices such as the V-chip and software to restrict Web surfing have been developed to limit minors' choices of media content.

MEDIA CHOICE PATTERNS BY AGE AND GENDER

Research on the actual content choices of children and adolescents encounters severe methodological problems. Very young children are not yet able to report

their likes and dislikes in a survey. Observational studies revealed that children pay more attention to television content that is easily understood. Salient formal features, such as sounds and strong visuals on television, attract the attention even of very small children, as more attention to content features starts around the age of 2 years.

A few experimental studies reviewed or conducted by Knobloch and colleagues presented media choices to preschoolers, who were allowed simply to select what they preferred. American children 2 to 4 years of age were asked to pick from a selection of books those they wanted to have read to them. As expected, girls preferred romantic tales, increasingly so with age. Boys especially liked horror and violent stories. Age did not influence their choices. Moreover, in a study in which videotape covers were presented to preschoolers in Germany, China, and the United States, boys uniformly favored violent entertainment, independent of country and age. Girls, on the other hand, preferred nonviolent videos and chose them more often than did boys. This cross-cultural investigation also found that girls and boys in all countries preferred entertainment featuring protagonists of their own gender. This finding supports the notion that children and teens look at media characters for orientation, as they prefer others like themselves.

A number of studies investigated young media consumers' choices through surveys. For instance, Valkenburg and Janssen found comprehensibility, action, and humor to be the entertainment program features most valued by children between 6 and 11 years. Again, boys were reported to be attracted by action and violence in children's programs, whereas girls attached more value to innocuousness and comprehensibility.

For teenagers, media selection patterns have been investigated along the lines of mood management theory and social perceptions, with an emphasis on music selections. Teens and young adults employ music to regulate and manage their moods. Music preferences, however, also help in forming impressions of others, as well as in presenting the self to others. These social–cognitive processes are based on associations of various traits with music styles and preferences for these styles.

A very important function of music for young people is the rebellion associated with it or explicitly expressed in it. Young people choose to listen to rebellious music to emphasize their identity and to distinguish themselves from authorities. In general, the more young media consumers aim to differentiate themselves from parents and other authorities, the more they are motivated to violate prescribed rules. This is reflected in the so-called forbidden fruit effect: Content that is said to be inappropriate for children or adolescents may instigate their curiosity. Hence, nonconforming choices of media content are an important topic throughout childhood and adolescence.

CIGARETTE ADVERTISING, EFFECTS OF

Cigarette smoking continues to be the number one preventable cause of death in the United States. Historically, more than 80% of all smokers began prior to age 18. Extensive research has been conducted on factors influencing the initiation and maintenance of smoking in adolescence, in hopes of identifying ways to decrease smoking behavior in the United States. However, adolescent rates of smoking have remained relatively stable since the mid-1970s, although rates of smoking have been declining slowly since 1997. Research suggests that, every day, an average of 3,000 adolescents become regular smokers, and 6,000 adolescents experiment with smoking.

The role that advertising plays in adolescent initiation of smoking has been an issue since the surgeon general's original report on the dangers of smoking in 1964. A number of studies have been conducted on the role of pro-tobacco advertising on general levels of smoking as well as the influence of tobacco advertising and promotions on adolescent initiation of smoking. At the same time, policymakers have realized that advertising may play an important role in countering smoking behavior. There have been two national anti-smoking advertising campaigns. The first was in the late 1960s. The second is the ongoing Truth campaign that is being conducted by the American Legacy Foundation. In addition, many states have utilized advertising in their anti-smoking campaigns.

PRO-SMOKING ADVERTISING

The amount spent on tobacco marketing increased twofold between 1998 and 2003. In 2003, the tobacco industry spent more than $41 million per day, for a total of more than $15 billion, on tobacco marketing in the United States alone. This spending includes advertising, price discounts, promotional allowances to retailers and wholesalers, bonus cigarettes in cigarette packs, and coupons. Indeed, in terms of money spent in 2003, advertising was not among the top five promotional activities undertaken by the tobacco industry.

The influence of tobacco advertising on tobacco use has long been a concern of policymakers. Critics charge that the tobacco industry has targeted children and adolescents with their advertising campaigns and that these campaigns have resulted in many adolescents becoming smokers. The tobacco industry, on the other hand, argues that their advertising campaigns are aimed at keeping smokers loyal to their brand or convincing other smokers to switch to their brand of cigarettes.

On January 2, 1971, a partial ban on cigarette advertising went into effect in the United States, with cigarette ads banned on television and radio. Many other countries have partial or complete bans on cigarette advertising as well. Additional restrictions were placed on tobacco advertising in the United States in 1998 when the Master Settlement Agreement (MSA) was signed between the tobacco industry and the attorneys general of the 46 states that had sued the tobacco industry. This settlement sought to stop the tobacco industry from targeting children and adolescents. In addition, the agreement resulted in the creation of the American Legacy Foundation, which was charged with establishing a nationwide anti-smoking campaign.

Despite the restrictions on advertising and promotions by the tobacco industry, children and adolescents continue to be exposed to cigarette promotions. In a study in New Hampshire and Vermont in the mid-1990s, approximately a third of the high school students owned a cigarette promotional device such as an ashtray, cigarette lighter, or article of clothing. Students who owned these promotional devices were four times more likely to be smokers. A more recent survey conducted in 2001 found that approximately one third of 12-to-17-year-olds reported seeing a print ad for cigarettes in the last month, and a little more than 40% of the adolescents reported exposure to some form of promotion in the last month. Interestingly, only 7% of students in this study reported owning tobacco promotional items, which indicates that the MSA is having some effect on adolescents' exposure to tobacco marketing. However, a disturbing and understudied trend is the use of the Internet to market tobacco products. In 2002, 42.7% of middle school students and 33.5% of high school students reported seeing tobacco products advertised on the Web. In 2004, the percentage of middle school

students seeing tobacco products advertising on the Web had dropped to 34.1%, but the percentage of high school students had climbed to 39.2%.

Three lines of research on the influence of pro-tobacco marketing are discussed in this entry. First, econometric research focuses on aggregate tobacco advertising expenditures and smoking rates. Second, researchers have looked at various indicators of the effects of tobacco advertising on children and adolescents specifically. Finally, some recent research has focused on the effects of susceptibility to tobacco marketing and smoking initiation in adolescents.

Econometric Research

Econometrics research on tobacco advertising has focused on two things: the effects of partial or complete advertising bans on the aggregate demand for tobacco products, and the effect of total monies spent on cigarette advertising on aggregate cigarette demand. Although this research does not focus on adolescent smokers or even on the number of people who actually smoke, it is still informative regarding the effects of tobacco advertising on overall demand for cigarettes.

Studies of the effect of aggregate levels of advertising in the United States, the United Kingdom, Australia, and Germany suggest that total expenditures for tobacco marketing explain only a small percentage of tobacco purchases. One estimate predicted that tobacco marketing accounts for as much as 7% of all smoking in Australia, but most estimates run much lower than this upper estimate. However, a study looking specifically at the marketing of cigarettes to women during the 1960s did find a substantial increase in female adolescent smoking rates that corresponded with advertising expenditures. Of course, this increase in smoking among adolescent females may be explained by the feminist movement, with its emphasis on independence—a characteristic that is often associated with smoking.

Research on ad bans has looked at countries with complete bans on tobacco advertising, such as Norway, Finland, Canada, and New Zealand, and partial bans, such as Australia and the United States. Typically, the research has found a small effect of the ad ban on total tobacco consumption, which is consistent with the finding that advertising has a fairly small effect on total demand for cigarettes. Interestingly, the advertising ban in Finland resulted in a 6.7% decrease in demand for cigarettes but a substantial increase of 26% in demand for cigars and pipe tobacco, suggesting that many smokers changed the tobacco product they used as a result of the advertising ban.

A particularly interesting argument concerning the partial cigarette advertising ban in the United States emerged out of the econometric research. One analysis found that the partial ban that went into effect in 1971 indirectly resulted in higher levels of smoking in the United States. Prior to the ban, the Federal Communications Commission had forced the major networks to run 1 minute of anti-smoking public service announcements (PSAs) for every 4 minutes of smoking commercials. This action resulted in the first national anti-smoking media campaign, and this campaign was successful at decreasing smoking. However, when the ad ban went into effect, the networks were no longer required to air the anti-smoking PSAs, and the ban effectively ended the anti-smoking campaign.

The econometric research suggests a small effect of advertising on demand for cigarettes. However, several things that need to be kept in mind regarding this research. First, the research typically focused on demand for cigarettes rather than the number of people smoking. The ad bans may have resulted in lower levels of smoking rather than decreased numbers of people smoking. Second, the econometric research is not concerned with why the ban worked, so little is learned about the psychological effects of cigarette advertising.

Pro-Smoking Advertising, Children, and Adolescents

Studies have explored various effects of cigarette advertising on adolescents and children. For example, studies found that children and adolescents have a good memory for cigarette advertising. Indeed, one study found that adolescent smokers have better memory for cigarette advertisements than do older smokers. Alarmingly, more than 80% of 6-year-old children could accurately identify Joe Camel—the mascot for Camel cigarettes—and this level of recognition was equivalent to the 6-year-old's identification of the Disney Channel icon (mouse ears). Likewise, a study of children between the ages of 6 and 17 in Scotland found that approximately one third of the children could accurately identify which cigarette companies sponsored various sporting events. More disturbingly, the sponsorship of sporting events seemed to influence

children's impressions of the different brands of cigarettes. Even children who did not understand sponsorship associated brands of cigarettes with attributes associated with the sport the brand sponsored, which suggests that cigarette promotions were influencing children's perceptions of smoking and smokers.

Of course, that fact that children have a good memory for advertisements does not mean that the advertisements are leading the children to initiate cigarette smoking. People remember many advertisements that do not influence their buying behaviors. But the research does show that the advertisements are getting through to the children and may be shaping children's perceptions of smoking. Furthermore, the research suggests that cigarette advertising may reinforce adolescents' smoking behavior even if it does not influence their smoking initiation.

Additional research cited as support for a causal relationship between cigarette advertising and adolescent smoking initiation includes a series of studies finding that the most heavily advertised cigarette brands were those most remembered and smoked by teens. This finding suggests that, at a minimum, cigarette advertising is influencing the brand choice of teens. On the other hand, however, the outcome may simply mean that teens are mirroring the adult smoking behaviors they observe.

Finally, a study in Australia found that middle school students who judged that cigarette advertisements made them want to smoke were more likely to be smokers 2 years later. This study estimated that cigarette advertisements were responsible for a 15% increase in adolescent smoking. On the other hand, those adolescents who judged cigarette advertisements as persuasive may already be forming intentions to begin smoking, so it is unclear whether the study actually measured the effect of cigarette advertisements on children's decision to smoke or whether the advertisements reinforced children who had already decided to smoke.

Receptivity to Tobacco Promotions

Receptivity to tobacco promotions is a measure developed in the mid-1990s to explore the effects of cigarette promotions on adolescent smoking. A five-item scale is used to measure receptivity to tobacco promotions. The questions focus on adolescents' ownership of or willingness to use cigarette promotional items, ability to name cigarette brands advertised, and ability to name the brand featured in their favorite cigarette ad. Studies have found that adolescents who are more receptive to tobacco marketing are more likely to be current smokers. Indeed, research suggests that receptive teens are four times more likely to be smokers. Of course, this finding is somewhat obvious in that we would expect smokers to be more willing to use smoking promotional items and to pay more attention to cigarette advertisements.

Several longitudinal studies have explored whether nonsmoking teens who are receptive to tobacco promotions are more likely to become smokers. These studies had lags of 21 months to 5 years between the initial measure of receptivity to tobacco promotions and follow-up measures to see whether the adolescents had either experimented with smoking or had become regular smokers. The longitudinal studies found that nonsmokers who were more receptive to tobacco promotions were more likely to experiment with smoking or to become established smokers than were nonsmoking adolescents who were not receptive to smoking. Indeed, one study estimated that 34% of experimenting with cigarettes was due to receptivity to tobacco promotions.

These longitudinal studies provide the best evidence to date that cigarette promotions influence adolescent smoking initiation. However, several problems with this research must be considered. There are numerous factors that influence adolescent smoking initiation. For example, having friends or family who smoke is consistently the strongest predictor of smoking initiation among adolescents. Interestingly, having family or peers who smoke is also strongly related to receptivity to tobacco promotions. Maybe receptivity is a by-product of having friends who smoke (and who also have promotional items and talk about ads), so that the real culprit is peer smoking behavior. Likewise, research has suggested that teens who are receptive to tobacco promotions have already decided to smoke and that their receptivity to tobacco promotions is a consequence of trying to learn more about smoking. According to this interpretation, the promotions may still play an important role in smoking initiation by reinforcing the adolescents' decision to begin smoking. Unfortunately, the research on receptivity to tobacco promotions is still fairly new, and more extensive studies are necessary to understand how receptivity interfaces with other factors that influence adolescent smoking, such as peer smoking.

ANTI-SMOKING ADVERTISING

The first nationwide anti-smoking advertising campaign began in the late 1960s and ended in 1971 when the partial ban on cigarette advertising went into effect. The research on teen smoking clearly shows that media campaigns can work. However, the research also suggests that media campaigns are more effective as part of a larger campaign that involves many different elements, including schools, community leaders, policy changes (such as indoor smoking restrictions), enforced restrictions on access to cigarettes, and taxes on tobacco products. Campaigns in Massachusetts, California, Mississippi, and Florida are examples of successful comprehensive anti-smoking campaigns.

Do the successful statewide campaigns indicate what kinds of messages are likely to be effective in combating teen smoking? There are many different anti-smoking appeals that can be used to counter adolescent initiation of smoking. Many of these strategies have been found to be effective in various campaigns. However, the statewide campaigns often involve several different themes that make it difficult to isolate which theme(s) are working. For example, the early California campaign included two major themes: the dangers of secondhand smoke and attacks on the tobacco industry. Because both themes were featured, it is impossible to establish whether one or both themes were primarily responsible for the early decrease in adolescent smoking rates in California.

However, experimental studies on the effectiveness of different types of anti-smoking ads with middle school and high school nonsmokers suggest that the dangers of secondhand smoke, social norm appeals, cosmetic appeals, and long-term health appeals work best with this audience. However, more research is necessary before any kind of scientific consensus can be reached on which appeals work best with adolescents. Indeed, there probably will never be such a consensus, because a successful campaign probably requires the utilization of many, if not most, of the different kinds of anti-smoking appeals. It is clear that more research is necessary for a better understanding of how the different appeals work and which appeals are more effective with particular adolescent audiences, and for identification of new appeals. It is also clear that there is no single effective way to prevent youth smoking. However, the evidence does show that different approaches can be effective.

The 1998 MSA with the tobacco industry resulted in the establishment of the American Legacy Foundation (ALF). ALF was charged with creating and overseeing a national anti-smoking campaign. ALF's Truth campaign is an ongoing national media campaign targeting high-risk adolescents. The campaign is primarily a countermarketing campaign focused on changing adolescents' attitudes toward the tobacco industry and on increasing adolescents' media literacy regarding tobacco marketing. The three primary themes across the different Truth campaigns are the tobacco industry's manipulative marketing to adolescents, the addictive nature of nicotine, and the long-term health consequences of smoking. An interesting component of the early part of the campaign was the desire to create a "truth" brand. Teenagers are very attentive to brand names. Consequently, if the campaign could create a brand that was anti-smoking and anti-tobacco industry, ALF felt that the campaign would be more effective. The campaign has clearly been very effective in creating a truth brand.

Has the ALF's Truth campaign been effective in decreasing teen smoking? The campaign has clearly influenced adolescent attitudes toward the tobacco industry. Teens who report greater exposure to the campaign also hold more negative attitudes toward the tobacco industry. However, do these attitudes translate into lower smoking rates? At this point, the data are unclear. Several studies published in 2002 suggest that the campaign had effects on adolescents' self-reported intentions to smoke. Two studies published in 2005 indicate that the campaign made adolescents less susceptible to tobacco marketing, which led to decreases in adolescent smoking rates.

Although the Truth campaign has been successful in changing adolescents' attitudes toward the tobacco industry and appears to have had an effect on actual smoking rates, three factors are important to consider when evaluating the effectiveness of the campaign. First, one of the 2005 studies found a curvilinear relationship between exposure to the campaign and declining smoking rates during the campaign. This result, if accurate, indicates that increased exposure to the campaign worked *up to a point* but that heavy exposure to the campaign may have actually backfired and was associated with higher levels of adolescent smoking. Second, although the campaign has had some effect, the effect is modest given the total resources provided to the ALF by the MSA. Although the limited effect of the campaign is disappointing, it should not be

surprising, because the campaign was not part of a comprehensive anti-smoking campaign. Prior research clearly demonstrates that anti-smoking media campaigns work best when they are run in conjunction with other anti-smoking programs, most notably school-based programs. Third, the long-term effects of the campaign are unclear because the funding provided by the tobacco industry as stipulated by the MSA has ended. Consequently, the Truth campaign will probably be much smaller in the future. In a similar situation, Minnesota's anti-smoking campaign was dramatically cut back in July 2003, and within 6 months of the end of the campaign, adolescent susceptibility to begin smoking had increased dramatically.

Adolescents continue to begin smoking at alarming rates. Many factors play a role in adolescent initiation of smoking. More research is necessary to understand how these factors interact with tobacco advertising to influence adolescent smoking. Fortunately, the media can play a critical role in combating teen smoking when used in conjunction with larger comprehensive programs. California is an example of how successful a multifaceted campaign can be at changing the prevalence of smoking and the cultural acceptability of smoking.

CIGARETTE ADVERTISING, HISTORY OF

Cigarette marketers have appealed to young people with many obvious practices, such as the use of youthful models, ads in media the audience of which is

exclusively or predominantly young, copy and art known to be attractive and interpretable to children (cartoons), and placement of ads in familiar contexts (such as cigarette ads in video games and candy cigarettes). However, advertising appeals to young people are not always so obvious. On the basis of careful research, advertisers have targeted youth with appeals designed to match their psychological needs and aspirations. For example, images of independence appeal to youth's need for independence. Similarly, advertising and promotion often pair cigarettes with things of great interest to the young, such as automobiles, other motor sports, popular music, and movies. Heavy media buying, coupled with in-store and on-street signage, can make a product attractive simply by virtue of being so well recognized that it becomes familiar and trusted. Ads to the young are not intended to be informative by voluntarily disclosing the risks of addiction or the many diseases and disabilities, such as impotence, to which smoking can lead. Indeed, because of the identity needs of adolescents, this age group may be particularly responsive to ads connoting style and symbolic product personality attributes, so ads make these appeals and do not offer any negative information about the product.

The young are a vital target market for the cigarette industry. Most smokers start as adolescents, and the addictive nature of nicotine leads to phenomenally high rates of brand loyalty among smokers. Cigarette companies need to replace smokers who quit, so getting replacement starters is important to them. Moreover, the deadly consequences of smoking create a chronic and substantial need to replace smokers who die. This combination of factors leads naturally to a strategic interest in replacement starters, as brands able to attract starters will enjoy the profitability of their brand loyalties for many years, sometimes for a lifetime. It is not surprising, therefore, that cigarette advertising has long been suspected of intentionally appealing to the young.

Industry documents now coming to light in courtroom trials show that firms have researched children as young as 11, 12 and 13 years, with target audiences starting at age 15. Images of independence and freedom from authority were used to capitalize upon the psychological needs of young starters. Crafting and pretesting ensured that the ad images were not too immature, lest the brand be rejected by teens seeking symbols of adulthood, and the activities not too aerobic, lest this be laughably unbelievable. Some ads stressed peer group acceptance, belonging, and security.

MEDIA CAMPAIGNS

At least since the 1920s, legislators and public heath officials have been concerned that advertising is "deliberate propaganda" creating an unnecessary appetite for smoking in young men and women. Cigarette firms, of course, vehemently deny that they have ever engaged in practices that targeted minors, but the historical record contradicts this. Magazine editors writing about business and advertising in the 1950s certainly saw advertising as "growing the market" by successfully recruiting children. Over the years, companies have used a variety of media to reach the youth market.

Popular Music

Cigarette firms were bold pioneers in the use of radio and, later, TV as advertising media. Cigarette firms sponsored musical shows such as Lucky Strike's *Your Hit Parade,* which reviewed the top popular music hits of the week. Many famous big bands popular with the young—such as those led by Benny Goodman, Glenn Miller, Paul Whiteman, Artie Shaw, and Tommy Dorsey—were sponsored on radio. In the 1940s, market research firms employed by cigarette firms studied the radio preferences and the musical shows and styles that appealed to "boys and girls." In the 1960s, cigarette firms bought a lot of ads on popular music programs that aired on radio in the afternoon just after school.

Comics, Cartoons, and the Circus

Kids were advertised to in the Sunday comics, TV cartoons, and circus programs, and even on school book covers and football programs. Several major firms advertised in *Puck: The Comic Weekly,* a syndicated collection that reached "virtually all the kids." Many cigarette brands sponsored cartoons, as Winston sponsored *The Flintstones* on television. Some created new comic strips just to promote their brands. One brand used Frosty the Snowman to sell cigarettes. Another firm had ads on plastic-coated book covers distributed in 8,000 high schools. Clowns and advertising in circus programs reached "children of all ages," and cigarette firms paid to be used in jokes by clowns in the Ringling Brothers' Barnum & Bailey Circus. In the 1990s, Camels were sold using a cartoon, Joe Camel, whose face was thought by some to look a lot like a boy's private parts. Researchers

showed that even preschoolers were aware of the Joe Camel campaign and that it was particularly well known and popular with the 12-to-14-year-olds.

Television

When TV became big in the 1950s, cigarette firms were very heavy sponsors, advertising on shows with young audiences such as *The Many Loves of Dobie Gillis*, *The Horace Heidt Amateur Hour* (a talent audition like today's *American Idol*), and *Your Hit Parade,* among many, many others. A cigarette brand sponsored the American debut of The Beatles on *The Ed Sullivan Show*. Programs such as *The Flintstones* and *The Beverly Hillbillies*, the audiences of which were nearly half minors, were sponsored by cigarette brands. There was so much TV advertising for cigarette in the 1960s that the average teenager saw more than 1,000 TV ads for cigarettes every year; preteens, those ages 2 to 12, saw nearly as many. This made teenagers appear to be the prime target for TV cigarette advertising.

Sports

Cigarette brands sponsored most baseball broadcasts, the National Football League, college all-star games, and even the Olympics. Marlboro gave prizes to the "Rookie of the Year," and sports superstars such as Mickey Mantle, Roger Maris, Frank Gifford, Joe DiMaggio, and Hank Aaron appeared in ads endorsing cigarettes, as did many other professional athletes, especially Major League baseball players.

Candy Cigarettes

Five different manufacturers of candy made candy cigarettes that closely imitated most popular brands, and this practice continued into the 1980s without the cigarette firms ever taking legal action against the obvious infringement of their copyrights. In similar copyright infringements, cigarette ads appeared in video arcade games.

Movies

Moviegoing, highly popular with dating teenagers, attracted cigarette posters placed in movie theaters, ads in free magazines, and ads shown before movies, including one showing a rerun of *Snow White and the Seven Dwarfs*. Movie producers were paid to rewrite scripts to include shots of cigarette billboards and to make nonsmokers into smokers. Superman's girlfriend, Lois Lane, was turned into a smoker for *Superman II*.

Driving Passions

Marlboro and other brands capture the driving passions of the young by sponsoring racing drivers, teams, events, and whole series for a wide variety of vehicles: Formula One cars, Indy cars, road rallies, speedboats, drag racing, the GT and GTO series, motorcycles, monster trucks, and stock cars. One campaign that drew much criticism for its copy was Lucky Strike's campaign slogan, "Luckies separate the men from the boys, but not from the girls." A typical ad showed a young man looking longingly at a mature man, such as race car driver, simultaneously enjoying a cigarette, a victory trophy, and the admiration of an attractive woman.

Marlboro's Independence

Marlboro's success among the young is due in large part to the mythology of the cowboy in its image-based advertising. Marlboro was once sold as a female product with the slogan "Mild as May." After spending a small fortune on consulting psychologists and market research, the durable cowboy of Marlboro Country, with his rugged individualism, became the perfect symbol of independence and individualistic rebellion, well suited to the teenage desire to be grown up and independent, free from parents and teachers. The Marlboro man is consistently portrayed in ways that emphasize his independence. He is almost always alone and is never subject to any authority whatsoever or even in its presence. There are no parents, no older brothers, no foremen, and no bullies in Marlboro Country. Marlboro Country doesn't even have a sheriff! The power of this image advertising has been demonstrated by Marlboro's success in capturing the biggest share of starters every year, starters whose brand loyalty soon made Marlboro the best seller overall.

Virginia Slims

The stunning success of Marlboro advertising led Philip Morris to launch a second brand with the imagery of independence, this one with a female personality: Virginia Slims. As with Marlboros, careful research was done, leading to the pseudoliberated

slogan, "You've Come a Long Way, Baby." One ad executive stated that they wanted to tap the emerging independence and self-fulfillment of women to make smoking a way of expressing that.

CREATING "FRIENDLY FAMILIARITY"

Massive spending—more than $15 billion in the United States during 2003, according to the Federal Trade Commission—supports advertising and promotional activity to sell cigarettes. Until recently, cigarette and brand sponsorship advertising and signage was in many magazines, on billboards, on the interiors and exteriors of buses, in subways and transit shelters, through sports sponsorships, in sports stadia, on T-shirts and baseball caps, and in many other places. In retail stores, it appears on clocks, store-hour signs, retail displays, change trays, window decals, signage, posters, ashtrays, waste receptacles, shopping baskets, and pushcarts.

The result of pervasive and persistent cigarette merchandising and sponsorship advertising is that generations of young consumers have grown up immersed in an environment dense with cigarette advertising imagery. Each individual is likely to be exposed on a frequent and regular basis to all the common types of cigarette messages, whether images of independence, social approval, pictures of health, or other implied health reassurances. The net effect of this virtual omnipresence is what Marlboro ad agent Leo Burnett called "friendly familiarity," a judgment that the product cannot be all that bad because it seems to be such an accepted commonplace in society.

The conspicuous and persistent presence of advertising for tobacco products gives the impression, especially to children, that tobacco use is desirable, socially acceptable, and prevalent. It leads to the understandable but erroneous rationalization of consumers that "it can't be all that bad, since governments and the courts permit its promotion." The familiarity effect, wherein things encountered frequently are trusted as benign, just as the unfamiliar evokes suspicion, has become well recognized and researched in psychology since it was labeled by Burnett.

Industry observers noted that cigarette ads often portray and seem to be pitched directly at young people and that nowhere in that bright, wonderful world depicted in cigarette ads was there any hint that cigarettes might be harmful. The National Congress of Parents and Teachers described cigarette advertising as "smokewashing," invoking a parallel with psychological brainwashing.

The result of all of this advertising is that smoking is made to seem universally acceptable, attractive, and desirable. It affected the teenagers' judgments of the number of people who smoked, the status and social approval that smokers received, and the health of smokers. Cigarette advertising by its very nature inevitably glamorizes smoking, potentially influencing the young by shaping their perceptions that many attractive people are smokers, that smokers appear to be healthy, that smokers obtain social approval for their smoking, and that smokers are especially independent and self-reliant (despite their nicotine addiction). Teens, especially those depressed or unsure of their identity, are very susceptible to the images of romance, success, sophistication, popularity, and adventure that advertising suggests they can achieve by smoking cigarettes. Cigarette ads intentionally appeal to the adolescent need for independence. They also communicate to youth that cigarettes can be props for displaying what seems to be an attractive identity and maturity.

CIGARETTE USE, MUSIC VIDEOS AND

Although few studies on tobacco and cigarette use among adolescents have analyzed the use of tobacco products in music videos, a few focused investigations of music videos and tobacco usage have been conducted. These studies indicate that more than a fifth of music videos portray individuals smoking. Other research has dealt with the extent to which youth and adolescents watch music videos. Although the amount of exposure to music television reported by these investigations differs rather substantially, nevertheless it is clear that children and adolescents spend a great deal of time watching music videos. Repeated, regular exposure to poignant and credible multimedia materials by adolescents who are at critical stages of their socialization enhances the likelihood that depictions of tobacco use by media figures they idolize will influence the attitudes, morals, values, and behaviors of young music television viewers.

According to the Centers for Disease Control (CDC), every day in the United States alone nearly 4,400 young people between the ages of 12 and 17 years begin to smoke cigarettes, and every day approximately 2,000 other adolescents become regular, daily cigarette smokers. Among U.S. high school students, 22.9% are current cigarette smokers, with regular smoking relatively equally divided by gender (male = 24.6%, female = 21.2%). Among middle school students, 10.1% are current smokers (10.2% males, 10.0% females). For both age groups, Caucasians smoke at a slightly higher rate than Hispanics, African Americans, and Asian Americans. If such trends continue, the CDC projects that 6.4 million people currently under 18 will die prematurely from a tobacco-related disease. Such diseases include cardiovascular and respiratory illnesses, as well as lung, larynx, esophageal, and oral cancers.

A mid-1980s study of music videos found narcotics, stimulants, and other substances in 24% of the music videos on MTV. Almost a decade later, another study found that tobacco use was incorporated in 25.7% of the music videos on MTV. The latter study also found that the lead singer in the video was twice as likely to smoke, compared to a backup singer or other musician. Moreover, in music videos in which smoking was portrayed, young adults did 76% of the puffing. Ninety percent of the videos that featured smoking depicted at least one male smoking, and 41% portrayed at least one female smoking. In terms of smoking by music genre, 30.1% of the videos depicting smoking were of rap music.

A 21st-century study of tobacco use in music videos found a very modest decrease in frequency of smoking in music videos. Of the 258 videos analyzed, 21% had some sort of visual reference to tobacco. Of those videos showing tobacco use, 18% showed explicit tobacco use; moreover, 9% showed tobacco being used by lead characters or band members, whereas 13% featured tobacco consumption by secondary characters. In terms of the specific tobacco products consumed, cigarettes were shown in 60% and cigars were shown in 51% of the videos featuring tobacco products. Differences were found by music television networks and by music genre. Tobacco use was featured in 32% of videos on BET, 16% on VH1, and 11% on MTV. Analyzing by genre, tobacco appeared in 23% of rap and hip-hop videos, 18% of mainstream rock music, 17% of Hot-100 videos, and 18% of modern rock videos. Another important finding was that, when substances were portrayed, more often than not they seemed to be common elements of everyday activity—what people naturally do when they socialize. Smoking seldom led to consequences of any other kind (either positive or negative), and lead characters frequently used tobacco products.

Music television is an important medium in adolescents' lives. A 1997 Annenberg Public Policy Center survey found that 53% of 10-to-17-year-olds watch MTV regularly. A study from a decade earlier had found that 80% of 9th-to-12th-graders watch the channel, with an average viewing time of 2 hours per day. A 1996 study reported that 73% of boys and 78% of girls between 12 and 19 years of age watch MTV. Although the amount of exposure to music television reported by these investigations differs rather substantially, it is clear that children and adolescents spend a great deal of time watching music videos. Furthermore, 19% of all teens (and 32% of African American teens) have reported that music videos are

one of their most influential sources for finding out about new trends. Such repeated, regular exposure to poignant and credible multimedia materials by adolescents who are at critical stages of their socialization enhances the likelihood that depictions of tobacco use by media figures they idolize will influence the attitudes, morals, values, and behaviors of young music television viewers.

CIGARETTE USE IN TELEVISION AND MOVIES

Historically, tobacco companies have garnered considerable publicity for various cigarette brands through *product placement,* which entails efforts to have product exposure during television shows and movies. Philip Morris, for example, had product placement arrangements for the movies *License to Kill* (featuring James Bond) and *Superman II.* Internal tobacco industry documents, made available to the public from litigation, reveal that in 1983 Brown and Williamson agreed to pay $500,000 to actor Sylvester Stallone in exchange for his smoking the company's brands in a minimum of five feature films. Payments toward promoting tobacco products in television shows and movies are now prohibited in accordance with the 1998 U.S. Master Settlement Agreement, but many public health groups remain concerned about the continued frequency of tobacco depictions and how tobacco use is commonly portrayed, given the impact those positive smoking messages might have on adolescent initiation. The U.S. Centers for Disease Control and Prevention have identified tobacco portrayals in the movies as a major factor in adolescent smoking.

Content analysis is a commonly used research method for examining tobacco use frequency and portrayals in television shows and movies. For studies pertaining to television shows, prime-time programming has been the typical sampling frame, although some studies account for music videos, programming during Saturday-morning hours, corresponding commercials, fictional series and soap operas with the highest ratings, and programming shown on a public television network. For studies that assess tobacco use portrayals in film, "top-grossing" movies are usually selected to generate a sampling frame, yet a few studies have focused on children's animated films.

TOBACCO USE PORTRAYALS IN TELEVISION SHOWS

The frequency and nature of tobacco use portrayals have often been compared to alcohol use portrayals. Study findings reveal that tobacco is infrequently depicted compared to alcohol in television programming. Bradley Greenberg and colleagues, for example, analyzed the usage of alcohol, tobacco, and illicit drugs during the prime-time and Saturday-morning hours of the 1976–1977 and 1977–1978 television seasons. They found that, for both seasons, alcohol accounted for greater than two thirds of all coded substance depictions. Tobacco use incidents occurred on average 0.7 times per hour during the 1976–1977 season, whereas tobacco was depicted 0.48 times per hour during the 1977–1978 season, thus indicating that viewers typically watched 2 hours of television programming before observing a character smoke a cigarette, cigar, or pipe.

William McEwen and Gerhard Hanneman assessed prime-time television programming and found that, although tobacco use was not common among major characters, the way in which it was portrayed was noteworthy. No characters were observed to refuse tobacco, and the consequences of usage were rarely emphasized. The most frequently classified tone of tobacco incidents was humorous. Moreover, Jon Cruz and Lawrence Wallack found in their study that, for observed smoking acts, nearly two thirds of smokers were lead characters, and 70% were cast in strong and

enduring roles. Only one incident was observed in which it was evident that a smoker may desire to quit.

Warren Breed and James De Foe assessed the portrayal of drinking and smoking for situation comedies and dramatic prime-time programming from 1950 to 1982. They found that cigarette use steadily dropped during this time frame (by a factor of 6 in situation comedies and by greater than 12 in dramas). Cigarette acts were more frequently depicted within dramatic programming for all time periods. Interestingly, cigarettes were lit for 94% of the acts, whereas the remaining cigarette acts were classified as "prepared" to smoke. During the 1950–1963 time frame, several types of adult characters (including heroes, heroines, and villains) were depicted smoking. From 1964 to 1970, some primary characters and stars were still seen smoking, yet during the 1971–1977 time period smokers were typically villains or insecure characters. Scenes parodying cigarettes became apparent during the 1981–1982 time frame. Smoking depictions among doctors dramatically declined over the 33-year span.

Nevertheless, despite decades of declining tobacco frequency rates, more recent studies suggest an upswing in tobacco representations for television shows from the 1990s. Anna Hazan and Stanton Glantz examined fictional prime-time programming during the fall of 1992 and found that 24% of episodes included at least one tobacco event. Overall, 0.99 tobacco events were apparent during each hour of television programming. In drama programs, 1.13 tobacco events occurred per hour, whereas in comedies there were 0.86 events per hour. Smokers were predominantly male (outnumbering female smokers by more than a three-to-one ratio), white (78%), and middle class (42%). The researchers classified 92% of tobacco events as "pro-tobacco," and "good-guy" smokers (55%) outnumbered "bad-guy" smokers (45%).

TOBACCO USE PORTRAYALS IN MOVIES

Annemarie Charlesworth and Stanton Glantz provide a comprehensive overview of the literature pertaining to tobacco use portrayals in the movies. William McIntosh and colleagues, for example, analyzed 100 popular movies spanning 5 decades (1940–1989). They found that 21% of characters smoked at least once during the observed films and that smoking frequency among characters reached a high during the 1950s and a low during the 1980s. Characters who smoked were depicted as more sexually active and romantic than nonsmoking characters.

Anna Hazan, Helene Lipton, and Stanton Glantz assessed feature-length, top-grossing U.S. films from 1960 through 1990. Their key findings were these:

1. The overall rate of tobacco use remained virtually unchanged (despite a significant decline in smoking rates among the general U.S. population).
2. Smoking groups became larger, and smoking alone declined.
3. Smoking involving relatively young people (aged 18 to 29) increased.
4. Business activities were customarily the most popular smoking context.
5. Smoking by minor characters became more common, whereas smoking by major characters became less frequent.
6. Smoking was increasingly associated with hostility and stress reduction.

Furthermore, a gradual, consistent drop in the presence of ashtrays was noted. They found that, overall, films typically depicted smokers as middle class, successful, attractive, white, and male. Stanton Glantz, Karen Kacirk, and Charles McCulloch then extended this research by adding a random sample of films released during the 1950s and up to 2002. The rate of tobacco use per minute of film had reached a minimum during the 1980s but increased during the 1990s and early 2000s, reaching levels comparable to the 1950s.

Finally, Adam Goldstein, Rachel Sobel, and Glen Newman examined the prevalence of tobacco and alcohol use in children's animated films that were released between 1937 and 1997. They found that 56% of the films portrayed tobacco use, including all seven animated movies released during 1996 and 1997. Cigars were the most commonly depicted type of tobacco, followed by cigarettes and pipes, respectively. A diverse number of characters were associated with cigars, whereas cigarettes were often reserved for independent, sexy characters, and pipes typically denoted wise, sweet, or older characters. Since 1992, a trend has emerged that characters using tobacco were more commonly classified as good. While more than two thirds of animated films featured tobacco or alcohol use, none of them contained verbal messages about the negative, long-term health consequences of tobacco use or alcohol abuse.

Studies have assessed the frequency of smoking depictions in television shows and movies and have examined who is likely to smoke and how they are portrayed. Directors and producers may use cigarette smoke to enhance atmosphere, depth, or distance, or to focus attention toward a character's face. The cigarette is a classic *floating signifier,* indicating that cigarettes may be used to express a wide variety of meanings (both positive and negative), depending on the context of the situation and the character being developed or depicted. As with television, after decades of declining rates of tobacco depictions, more recent studies suggest an upswing in tobacco representations for movies from the 1990s and early 2000s, which contradicted smoking prevalence rates observed in society at large. When tobacco use is portrayed, negative consequences (i.e., the adverse social or health effects) rarely seem to be emphasized.

COGNITIVE DEVELOPMENT, MEDIA AND

Parents are often surprised at the way in which their child responds to a particular television show or movie. A 6-year-old, for example, may focus more on a character's pretty dress than on what the character is doing in a given scene. Or a 4-year-old may beg to watch the same movie on DVD for a third time in a row. These examples underscore how important it is to consider how children make sense of the media. As children mature, they develop different cognitive skills and strategies for understanding the world. Consequently, a preschooler is likely to have a very different reaction to the same program than an older sister or brother would. Since the early 1980s, media researchers have increasingly recognized the need to adopt a developmental perspective when studying young people's responses to the media. In doing so, studies have used principles of cognitive development to explore age differences in how children interpret and react emotionally to media content.

THEORIES OF COGNITIVE DEVELOPMENT

In the most basic sense, *cognitive development* refers to what a child knows and thinks and to how those mental processes or cognitions develop over time. When a child encounters a media message, he or she must engage in a number of mental operations. For example, when watching a television program, the child must first allocate attention to the multiple auditory and visual cues on the screen. This process is made more complex by the need to simultaneously tune out distracting cues in the environment, such as a talkative sibling or friend. Next, the child must sequence the major events or pieces of information into a story. Most television programs have plots and subplots that must be disentangled and ordered. Third, the child needs to draw inferences from the implicit cues in the program. Television shows jump from location to location, activities occur in the plot but are not always depicted on screen, and characters have dreams and fantasies that require "reading between the lines" to fill in missing information. Fourth, the child must draw on prior experiences and

acquired knowledge already stored in memory to help make sense of the program. For instance, a child who has visited New York City will have a better understanding of a news story featuring the terrorist attacks on the World Trade Center than will a child who has never left the state of Wisconsin. Finally, the child will evaluate the television program in some way. All of these tasks require cognitive skills and energy.

Several influential theories of cognitive development have been used to predict and explain changes in how children process the media. Jean Piaget's theory of cognitive development posits that children progress through stages of cognitive growth that apply universally to all children. Piaget argued that each stage is a precursor to the next and that the stages reflect qualitative differences in cognitive structures. The sensorimotor stage (0–2 years) involves knowing the world through overt behaviors such as sucking or grasping. The preoperational stage (2–7 years) involves the first use of symbols, such as words and other simple representations, to signify objects and events. The concrete operational stage (7–11 years) involves the ability to use mental operations or routines to think about objects and events in the world. And the formal operational stage (11+ years) involves the ability to employ highly abstract mental operations, such as hypothetical and logical reasoning, to problem solving. Media researchers such as Patti Valkenburg and Joanne Cantor have used these stages to predict, for example, how a preoperational child might respond differently from a concrete operational child to advertising and to frightening programs.

Some developmental psychologists have criticized Piaget's theory on the grounds that his stages are too rigid to account for the variation that often exists in a child's abilities across different domains and topics. The information processing approach is a more recent perspective in developmental psychology that focuses more on the steps involved in cognitive processing than on cognitive structures per se. Information processing theories attempt to identify the precise mental processes that occur when a child encounters, transforms, and stores information in memory in response to the environment. Researchers using this framework examine how children encode information, what types of mnemonic strategies children use to store and retrieve information, how children develop mental scripts and schemas to represent information in memory, and how mental capacity to engage in such cognitive tasks develops over time. In the realm of media, researchers have used information processing to explore the impact of violent programming on the development of aggressive scripts in children's memory, children's comprehension of educational programs such as *Sesame Street,* and children's recall of news stories in the media.

Whether children's development is described by stages or by computer simulations, it is certainly complex and often uneven. One day, a child may appear unusually mature as he or she pours over websites about the planets, and the next day the same child may become engrossed in an animated cartoon like *SpongeBob SquarePants.* One way to conceptualize development, then, is to think about broad shifts in cognitive processing rather than abrupt and fixed stages at specific points in time. Some of these shifts occur during the transition from early (2–7 years) to middle childhood (8–12 years), and others occur during the transition from middle childhood to adolescence (13–17 years). The cognitive shifts described below are particularly relevant for understanding how children interact with media.

EARLY TO MIDDLE CHILDHOOD

From Perceptual to Conceptual Processing

Preschoolers pay very close attention to how things look and sound. This characteristic has been labeled *perceptual boundedness* by psychologist Jerome Bruner. For example, children below the age of 6 or 7 typically group objects by color or shape. As they grow older, they focus more on conceptual properties, such as the functions that objects share. Applying this idea to the media, research shows that younger children pay strong visual attention to salient features of a television program, such as animation, lively music, and sound effects. As children progress to middle childhood, they become more selective in their attention, searching for cues that are meaningful to the plot rather than those that are mesmerizing.

From Perceived Appearance to Reality

Another cognitive skill that develops during childhood is the ability to discriminate fantasy from reality. Very young children often attribute life to

inanimate objects and have imaginary friends, reflecting their naïveté about what is real. In fact, preschoolers will readily talk to the television screen and wave to characters. In one study by John Flavell and his colleagues, many of the 3-year-olds reported that a bowl of popcorn depicted on television would spill if the set were turned upside down. By age 4 or 5, children begin to understand that what is on television is a representation of real life, but they tend to assume that what *looks* real is real. In other words, they look for striking violations of physical reality to make judgments. Therefore, cartoons are likely to be judged as unreal simply because the characters are animated. Yet, animated characters can still be potent role models for younger aged children, reflecting the fragile nature of reality judgments in early childhood.

By age 7 or 8, children begin to use multiple criteria for judging reality in the media. They are able to consider the genre of the program, production techniques, and even the source of the message. Older children are most likely to judge a program, a movie, or even a videogame as realistic if it depicts characters and events that are *possible* in the real world.

From Concrete to Inferential Thinking

A final cognitive trend that has implications for the media is the shift from concrete to inferential thinking. Younger children tend to focus on information that is fairly explicit and tangible. Therefore, they are more likely to focus on a character's behaviors, which are fairly salient and concrete in nature, than on a character's motives. Yet, full comprehension of most media messages requires an ability to extract information that is implied but not explicitly presented. For example, television series require viewers to track and connect multiple storylines in an episode, websites do not overtly reveal their commercial purposes, and even video games convey implicit information about space and time. By age 8 or 9, children show dramatic improvements in their ability to link scenes and subplots together and to infer causal and time-order connections from media content.

MIDDLE CHILDHOOD TO ADOLESCENCE

From the Real to the Plausible

As described above, older elementary school children use a variety of cues to judge reality, but in the end they tend to focus on whether an event or character is *possible* in real life. As children move toward the teenage years, they become even more discriminating, judging media content as realistic only if it is *probable* or likely to occur in real life. This trend is consistent with adolescents' ability to engage in more abstract and probabilistic thinking, as outlined in Piaget's stage theory. In support of this idea, one study by Barbara Wilson and her colleagues found that teens were less frightened by stories of child kidnapping featured in the news than were older elementary school children, presumably because adolescents are capable of discounting such events as unlikely to happen to them.

From Empirical to Hypothetical Reasoning

A related shift that occurs between middle childhood and adolescence is from empirical to hypothetical reasoning. Older children are capable of conceptual reasoning, but it is often tied closely to observable information. So, for example, they may be able to draw inferences from a plot, but they are likely to have difficulty imagining alternative scenarios. In contrast, adolescents are increasingly able to comprehend abstract concepts, use formal logic, and think about hypothetical outcomes. Thus, teens can think more flexibly about media stories, conjure up alternative interpretations, and critique media content in terms of its source and its intended target.

Metacognitive Thinking

Metacognition refers to the ability to understand and alter one's own thought processes. Younger and even older children have difficulty considering their own cognitive processing, in part because it requires so much mental energy just to track the environment. But as they move toward adolescence, cognitive skills become more routinized, and higher-order thinking is possible. Teens and adults are often able to contemplate their own feelings and reactions to a situation at the same time that they are also processing what is happening in the environment. Thus, a teenager is more likely than a child to realize that loud music can interfere with the ability to read a complex novel. A teen will also be better able to monitor his or her emotional reactions to an upsetting movie or news story, and can even engage in "self talk" to reduce anxiety. Adolescents' awareness of the demands of

different media can affect the depth of processing they will use and in turn can increase their comprehension of complex material.

To summarize, cognitive shifts that occur during childhood and adolescence have important implications for how youth will respond to the media. When watching a violent TV program about a superhero, for example, a preschooler is likely to focus on the most striking perceptual features in the show, such as the way the hero looks and what he does. The preschooler also will perceive the program as fairly realistic, will mostly remember the violent actions displayed, and will have difficulty tracking the plot over time. An older child, in contrast, would appreciate more conceptual aspects of the program, such as the superhero's motives, his feelings, and even how other characters respond to him. An older child would also be able to track the main plot and any subplots in the episode. And the older child would likely discount the program as unrealistic because of the superhero's abnormal powers. Adolescents, on the other hand, would probably find such a program uninteresting. If they tuned in, they would be capable of criticizing the program at a more abstract level, looking at how gender or race is portrayed or how violence is reinforced as a problem-solving technique. They could also imagine alternative plot configurations. Clearly, developmental factors related to cognition are crucial in appreciating how a child will respond to a particular media experience.

COGNITIVE SCRIPT THEORY

Cognitive script theory refers to hypothesized knowledge structures that outline how everyday events unfold. Roger C. Shank and Robert Abelson's early work on script theory explores how these mental structures organize knowledge and inform our understanding of the world. Most media research on cognitive scripts has applied L. Rowell Huesmann's information processing model to explain how television content can influence children's behavior.

DEFINITION OF COGNITIVE SCRIPTS

Shank and Abelson define *cognitive scripts* as related sequences of actions that characterize frequently experienced events and, in turn, guide expectations and behaviors in everyday situations. The recurring experience of a particular event creates an internalized "template" of the likely sequence of actions, participants, and props within that situation. A restaurant script, for example, contains a basic series of events that typically occur in a restaurant (ordering food, eating a meal, receiving a check, and paying a bill), a cast of regular characters (hostess, waitress, busboy, and patrons), and common props (menus, plates, glasses, tables, and chairs).

Cognitive scripts are useful mental mechanisms because of their cognitive efficiency. Initially, the acquisition of new scripts may require conscious and effortful cognitive processing and resources.

However, once learned, cognitive scripts become part of long-term memory and can be applied to everyday situations with mental ease. As a result, people do not have to encounter each event as a new situation requiring a great deal of mental effort. Instead, cues within the environment activate a previously acquired script automatically and effortlessly. Furthermore, cognitive scripts can be generalized to a degree, allowing for flexibility within a range of similar events. For example, a restaurant script for an Italian restaurant can be applied to a Mexican restaurant because both environments encompass similar courses of events.

MEDIA AS TEACHER

In using Huesmann's information processing model to examine the effects of television content, researchers havesame time. Not surprisingly, research conducted on college students suggests a positive relationship between game playing and visual attentional skills. In a recent study of college students, video game players (who had played action video games at least 4 focused particularly on how violent content can influence children's behavior. Huesmann's model draws from Shank and Abelson's work on cognitive script theory and from Albert Bandura's observational learning theory to elucidate the processes involved in of media-based scripts over time that direct their behaviors, expectations, and outcomes in real-life situations.

THE ACQUISITION OF NEW SCRIPTS

Children do not necessarily learn from everything that they watch on television. Huesmann believes that new information is retained only if it is integrated through an encoding process by which the information is mentally represented and then stored in long-term memory. To encode a new script, a child must first attend to the presented sequence of actions. Attention to televised scripts depends on a program's saliency, distinctness, and relevance to the child, including the child's identification with the character and the perceived realism of the program. The encoding process then requires a child to rehearse the script by ruminating or acting it out in order to commit the script to long-term memory. The more a child rehearses a particular script, the more accessible it becomes to the child, and the more likely the child is to apply the script to future situations.

Activation, Retrieval, and Application of Scripts

Once a script is learned, its activation, retrieval, and application occur automatically and effortlessly. According to Huesmann's information processing model, there are five steps by which this recall process occurs: (1) A child must be confronted with a specific situation; (2) the child must evaluate the most salient cues in the environment to activate potential scripts that match the situation; (3) the child then retrieves a variety of scripts and evaluates their effectiveness to navigate the situation at hand; (4) the most suitable script is selected; and (5) the script is applied to guide behavior.

Huesmann's script-based theory illuminates the process by which children acquire aggressive behaviors from television violence. Research shows that, the more children watch violent content, the more likely they are to home in on the violent acts portrayed on television, activate violent scripts, and act out aggressively after viewing.

COGNITIVE SCRIPTS, TELEVISION VIOLENCE, AND CHILDREN

There is strong evidence that media teach children new behaviors, especially aggressive behaviors. An overwhelming number of studies have shown that exposure to television violence promotes short-term and long-term aggression among audiences. Preschool-age children seem to be particularly vulnerable to television violence because violent content is often highlighted by the qualities that attract young children's attention, such as fast pacing, loud sounds, and music. Since preschoolers have difficulty understanding subtle qualities of content, such as character motivation, narrative inference, and consequences of behaviors, they may not understand the complexities involved in a character's behavior or its consequences. Instead, children may attend only to the rewards received by aggressive acts. Therefore, repeated exposure to violent content can lead to children to develop maladaptive scripts in which aggressive behavior is deemed an acceptable way to navigate situations. These maladaptive scripts, committed to long-term memory in childhood, can continue to produce patterns of aggressive behavior throughout adulthood.

COGNITIVE SKILLS, COMPUTER USE AND

Does computer use affect cognitive skills? The reasoning behind this question is that use of a tool such as the computer requires specific cognitive skills, so repeated use of the tool may have an effect on those skills. Research addressing this question has mostly focused on the informal uses of the computer within the home, such as computer and video games. Although these studies have focused simply on cognitive skills, two lines of research are evident. One line of research has focused on generalized cognitive skills and school readiness and typically has used standardized tests. The other line of research has focused on specific skills, such as eye-hand coordination, divided visual attention, spatial skills, and iconic representation; these skills are crucial to most computer applications, such as video and computer games as well as the Internet.

COMPUTER USE AND GENERALIZED COGNITIVE SKILLS

Although the findings from the first line of research are limited and somewhat contradictory, they seem to indicate that computer use enhances skills such as alphabet recognition, counting and premathematical knowledge, concept learning, and language scores. For instance, one study found that, although computer exposure during the preschool years was related to the development of preschool concepts, the frequency of such use and household ownership of electronic and video games was not. Other studies suggest that home computer use may be positively linked to academic performance—for instance, well-controlled studies have shown advances in reading and mathematics, computer knowledge, following directions, grammar, and school achievement tests. Although these latter studies involved after-school computer use, the informal nature of the after-school context mimics the informal use of computers within the home.

COMPUTER USE AND SPECIFIC COGNITIVE SKILLS

The second line of research has focused mostly on popular action games played either on the computer or on specialized game systems such as Nintendo. These games contain rapid movement, extensive visual imagery, and intense interaction, plus various activities occurring simultaneously at different locations on the screen. Studies indicate that children who play such games can improve specific cognitive skills, such as eye-hand coordination, visual attention, spatial skills (e.g., three-dimensional representation of space and judgment of speeds and distances), and iconic representational skills.

One important skill utilized by most action games is eye-hand coordination, which is the rapid translation of visual information into motor actions by the hand. It is also a skill critical for many occupations, such as dentistry, surgery, and machine operation, and for athletic activities of all kinds. Research suggests that action games do have a positive effect on eye-hand coordination as measured in tests involving moving targets.

Another skill required for playing computer and video games is divided visual attention, which is skill at keeping track of multiple things happening simultaneously—not unlike a pilot's keeping track of a row of several engine dials simultaneously. Most action games frequently have more than one entity present and acting on the screen at the same time. Not surprisingly, research conducted on college students suggests a positive relationship between game playing and visual attentional skills. In a recent study of college

students, video game players (who had played action video games at least 4 days per week for a minimum of 1 hour per day for the previous 6 months) had enhanced attentional capacity compared to non–video game players (who had had little or no video game usage in the previous 6 months). Attentional capacity was measured on the computer in this study as well. In a follow-up study, subjects who received training on an action video game (*Medal of Honor*) for 10 consecutive days showed greater improvement in attentional strategies than those who played a puzzle game (*Tetris*). In contrast to the action video game, which was a battle game in which multiple entities were simultaneously engaged in various actions, *Tetris* was a dynamic puzzle game in which only one event took place at a time.

It is important to note that strategies for dividing visual attention have become necessary both for viewing television and for using computers. In the case of television, it is commonplace to have divided screens, with textual information running across the bottom simultaneously with the main program on the screen. In computer use, youth often move from window to window, simultaneously monitoring their instant messages, email, and homework while at the same time downloading music videos and watching television.

Spatial skills are a suite of skills that include skills such as mental rotation, spatial visualization, and the ability to deal with two-dimensional images in a hypothetical two- or three-dimensional space. Spatial skills are required by many, if not all, action video games, and research suggests that action games do help to improve spatial skills. For instance, video game playing has been found to enhance the spatial ability to mentally rotate three-dimensional objects in fifth-, seventh-, and ninth-grade students. In another study, on $10^{1/2}$ to $11^{1/2}$-year-olds, practice on a computer game (*Marble Madness*) reliably improved spatial performance (e.g., anticipating targets, extrapolating spatial paths), compared to practice on a computerized word game called *Conjecture*. *Marble Madness* required players to guide a marble along a three-dimensional grid using a joystick; the player had to keep the marble on the path and prevent it from falling off or being attacked by intruders. Another important skill required by action games is creating two-dimensional representations of space. Typically, the action takes place in a virtual space, and players must form a mental representation of the whole space and understand how each screen relates spatially to other parts of the space shown on different screens. Although there has been no research examining this skill, it is likely that computer use enhances it as well.

A final skill examined in the research is iconic representation, which is the ability to create and read images, such as pictures and diagrams. Iconic images are embodied in most computer applications and are frequently more important than words in many action games. Research with college students has found that that playing a computer game helped shifted representational styles from verbal to iconic. Game playing not only made participants create more iconic representations, it also seemed to make them understand iconic representation better.

It is important to note that the findings of extant research on the question of computer use and cognitive skills suggests only that computer game playing may enhance a particular skill if the game utilizes that skill and if the child's initial skill level has matured to a certain level. Furthermore, research has examined only the immediate consequences of computer use and has not systematically examined the long-term effects of computer use on cognitive skills. Finally, the research has not examined the effects of newer computer applications such as the Internet on specific cognitive skills.

COMIC BOOKS, SUPERHEROES IN

The superhero is a 20th-century American construction. Although it has ancient roots, the first superhero figure was Superman, who has remained a popular figure since his appearance in 1938 and has been marketed at various times to children, adolescents, and adults. Although superheroes continue to fascinate Americans, they also remain important commodities, constantly reinvented to meet shifting cultural attitudes.

EARLY SUPERHEROES

Although traces of modern-day superheroes such as Superman, Batman, Spiderman, and Wonder Woman can be found in ancient Greek and Roman myths, 18th-century gothic romance novels, late 19th- and early 20th-century science fiction, pulp and dime-store Westerns, and detective stories, the superhero figure itself did not emerge until 1938, when DC Comics featured Superman on the cover of Action Comics #1. The immediate success of this title quickly overtook the nascent comic-book industry, and the superhero became a mainstay.

Because superheroes first appeared in comic books, it has been assumed that these figures primarily appealed to young children. This assumption has also led to explanations of their appeal in terms of fantasies of adulthood bestowed upon their young readers. One of the most popular superheroes of the 1940s was Captain Marvel, whose secret identity was cub reporter Billy Batson. By saying the word *shazam*, Billy could become the all-powerful, adult Captain Marvel. Another related explanation has suggested that superheroes fulfill the family romance fantasy for children, providing self-reassuring answers to questions of where they came from and why they are different from their parents. This reinterpretation of Freud has worked particularly well when applied to Superman, an alien from another planet who is adopted by the Kents and therefore not doomed to suffer their frailties. In other words, superheroes constitute ego ideals for young children. Peter Middleton has argued that superheroes actually provide a road map of sorts for children seeking to learn about the adult world and that, for their adult creators, they serve as fantasies that are purposely all-powerful because they compensate for the failures of adult manhood to live up to its promise.

Although superheroes such as Superman may be attractive as sources of narcissistic identification, they also problematize this identification by marking their hero as explicitly "other." Superman, particularly in his latter-day incarnation, is often situated as an outsider and an illegal alien—what is more, one who feels guilty having wrought danger and destruction by his arrival on Earth (on *Smallville,* he blames all the kryptonite-related disasters on his arrival). It is often their guilty consciences that motivate superheroes to take action. Also, although victory is all but assured, it is never complete; there will always be a new challenge or a new villain, marking their control as partial at best. Superman could easily take over the world but purposely chooses to remain a loyal American citizen. Thus, narcissistic identification with such a figure may involve fantasies of self-control and, more accurately, self-denial more than fantasies of power, omnipotence, mastery, and control.

Beyond such criticisms of the family romance myth, claims that superheroes appeal only to children are ahistorical and inaccurate. There is much evidence to support the claim that comic books were never truly intended to be consumed only by younger readers. A large market for Superman during World War II were soldiers overseas. One in every four magazines shipped to soldiers was a comic book, including 35,000 copies of Superman each month. Although the comic-book industry clearly courted the juvenile market, business watchers in the postwar years also recognized comic books' appeal to young adults and the role of the war in creating a "captive market" of soldiers. The Market Research Company of America reported that, in 1945, 95% of boys and 91% of girls aged 6–11 read comic books, but so did 87% of boys and 81% of girls aged 12–17 and 41%

of men and 28% of women aged 18–30, suggesting that the market appeal crossed both gender and generational lines.

SUPERHEROES IN THE POST–WORLD WAR II ERA

Yet, even as comic-book sales continued to increase through the 1950s, superhero popularity began to dramatically decrease in the postwar years. While Superman, Batman, and Wonder Woman persisted, DC cancelled almost all of its other superhero titles. The decline in superhero popularity has been attributed to a flooding of the market in the immediate postwar years with derivatives by new publishers seeking to capitalize on the industry's success, as well as a growing conservatism within the publishing houses, which curbed innovation. Superhero decline also spoke to a shifting public mood in the postwar years, to which costumed heroes could no longer speak. Historian Bradford Wright suggests that the Allied victory in World War II seemed to create a world in which the goals of superheroes had been achieved, and that the public interest in such heroic figures consequently declined. Superhero comic books were replaced by a variety of new genres aimed at a differentiated and diverse potential audience; such genres included true crime, romance, horror, war, and lighthearted teen humor.

There can be little doubt that the industry's genre diversification and embrace of more adult-themed comics in the late 1940s was motivated, in part, by its desire to cater to these different groups as well as its recognition that its younger audience base was getting older and needed to be maintained. Yet, external threats of censorship and struggles to define its audience have also characterized and impacted the development of the U.S. comic-book industry. As early as 1940, critics such as Sterling North were calling comic books a "national disgrace" and accusing them of exploiting children's newfound consumer power (many preteens and teenagers saw an increase in the size of their wallets during the Depression and war years, as the collapse of the economy and enlistments in the armed services meant that more of America's youth entered the job market). North's arguments point to the assumed juvenile audience to which comic books catered. The early connections made by critics between comic books and the threats they posed to American youth would dog the industry and shape its direction in the years to come.

In the postwar years, public concerns shifted toward juvenile delinquency, and the comic-book industry, along with motion pictures and broadcasting, fell under scrutiny. Militant opponents of comic books, such as Gershon Legman and Dr. Frederick Wertham, emerged in the late 1940s and early 1950s and held great sway in public debates and congressional hearings. Wertham's 1954 *Seduction of the Innocent* was a best-selling attack on comic books. In 1948, more than 50 U.S. cities enacted legislation to ban comic-book sales to minors (once again hinting at the adult audience comic-book publishers were actually targeting alongside youth).

REGULATION OF COMIC-BOOK CONTENT

It was not until 1954, however, when the U.S. Senate Subcommittee to Investigate Juvenile Delinquency turned their attention to the comic-book industry, that a permanent self-regulatory body—the Comics Magazine Association of America (CMAA)—was established. The CMAA code was extremely restrictive. Wright has argued that the comics' code was introduced into the industry at a moment when other media were just beginning to recognize the youth market's potential and that it greatly hampered the comic-book industry's ability to compete. The CMAA responded to public concerns over the threat comic books posed to children and, in the process, contributed to the medium's juvenilization of its subject matter. As part of their efforts to avoid legal censoring, comic-book publishers reinstated their superhero titles, this time with a clear child market in mind. The successful licensing of Superman products, as well as sponsorship by the Kellogg Company of the Superman radio series and *The Adventures of Superman* TV series, also played an important role in refocusing the character toward children, as this was the breakfast-food company's (not the comic-book industry's) target market.

The CMAA's efforts to childproof the medium were relatively short-lived, as Marvel Comics established its popularity in the early 1960s by directly targeting teenagers and college students. Marvel superheroes such as Spiderman and the X-Men were teenagers themselves and suffered from various adolescent anxieties about self-image, self-confidence, and romantic failures. Meanwhile, Marvel's publicity machine exploited the company's anti-establishment reputation to make its product appealing to 1960s college students beginning to take part in civil rights and counterculture

protests. Others have pointed to the appeal of comic books and superheroes to the emergent pop art movement of the 1960s and its potential for exploitation by culture industries. This further suggests that the child-like appeal of comic-book heroes in the 1950s and 1960s did not easily equate with their marketability solely to children. By the 1980s, comic-book specialty shops had become the primary distribution outlets for comic books; independent publishers dealt in more controversial subject matter; and the collector's market transformed comic-book acquisition into big business for investors. The medium's adult market became the industry's primary target once more; historically, this market had never truly disappeared, although efforts to exploit it had been greatly constrained.

CURRENT TRENDS

With the increasing trend toward conglomeration of media industries since the 1970s, superheroes have seen a revival in various mediated forms, including motion-picture franchises (Batman, Superman, Spiderman), television series (*Smallville*), and cartoons (*Justice League, Teen Titans*), as well as new popularity for comic books (Marvel's Ultimates line has reinvented their classic heroes for a new generation of teenagers). Contemporary takes on superheroes either have either a cynical, darker side to their heroics or have nostalgically remembered them in simpler forms from eras gone by (or both; while *Smallville* plays up Clark Kent's adolescent angst and guilt, it is also set in a Rockwellian 1950s American town under constant threat from urban industrialists).

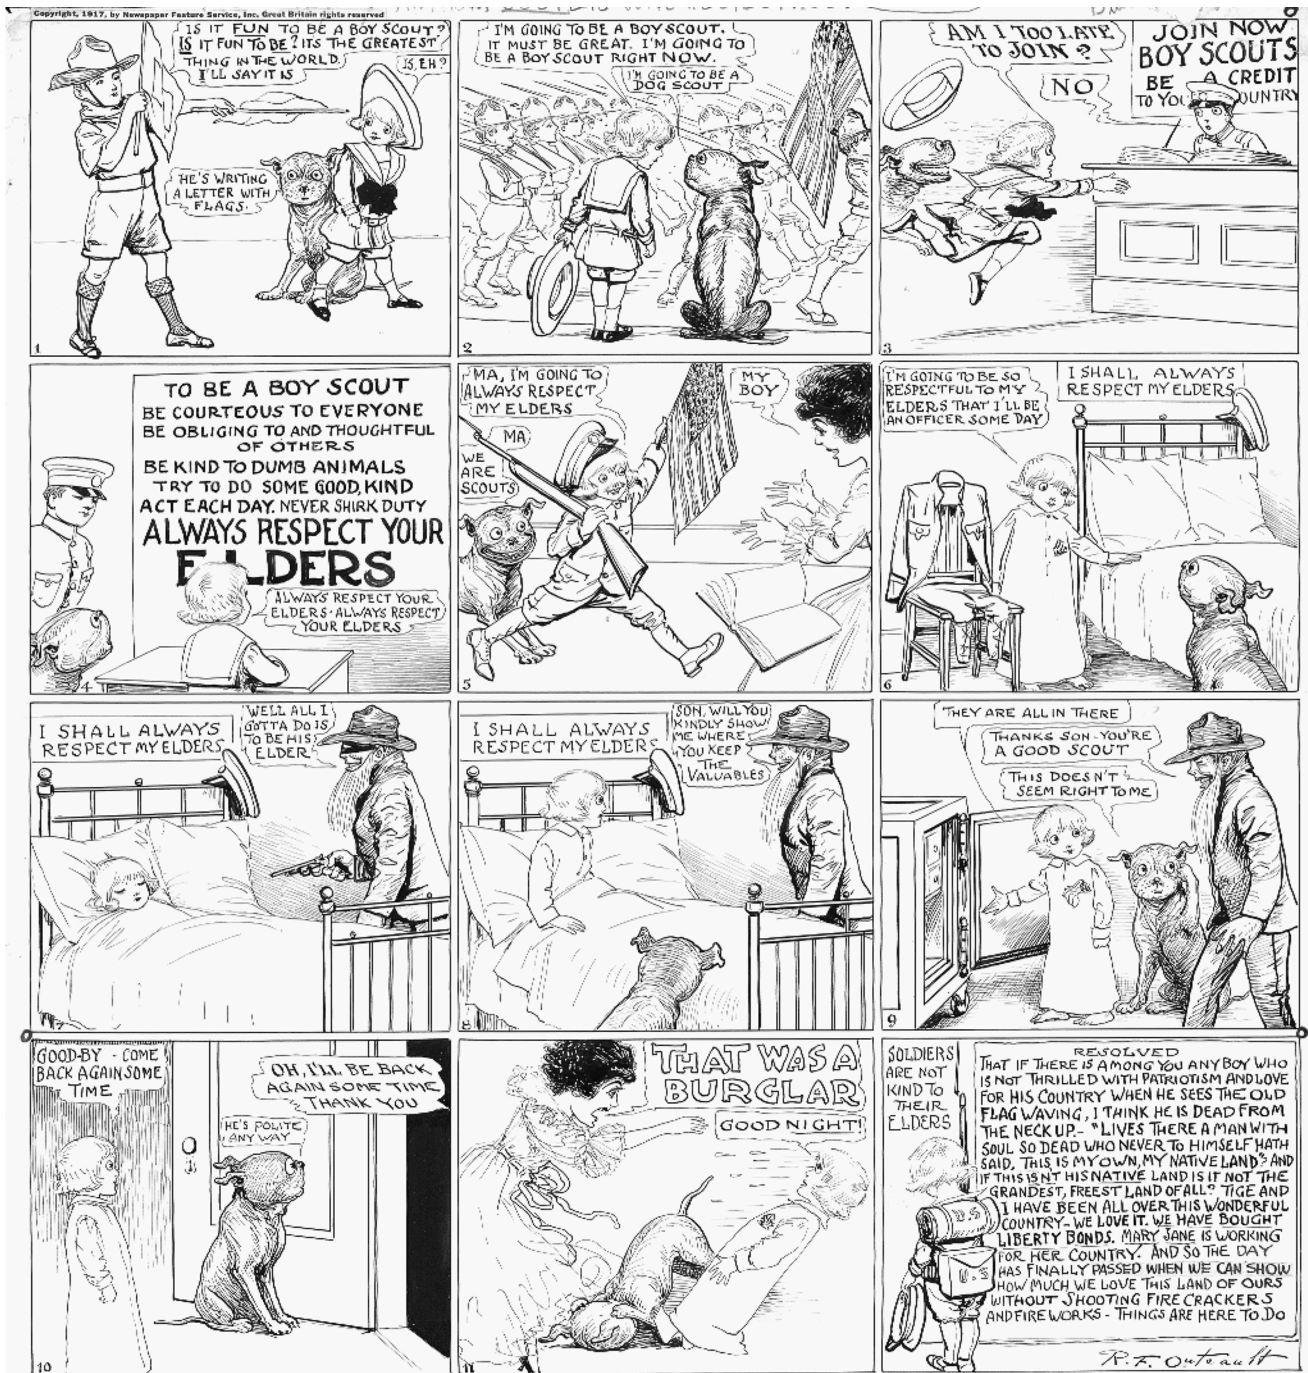
COMICS, DAILY NEWSPAPER

Children, teens, and youth cultures have been central preoccupations of comic strips and their critics since the development of the medium at the end of the 19th century. In the 20th century, there were debates as to whether the stories and images depicted—many of them featuring children—were an antidote or a symptom of a decline in cultural standards and moral values in the wake of a new era of mass culture. By the end of the 20th century, these concerns were replaced by a growing lament that the American comic strip had stagnated and no longer held the American public's attention the way it once had. As in the previous century, there are complaints that the comics have become more commodity than art form. Such arguments fail to take into account the subtle shifts that have been infused into comic strips, particularly those featuring children, over the past few decades, nor do they recognize the continued popularity of many comic strips in other media, sustained through increasingly synergistic cross-promotional and intertextual marketing strategies in an age of media conglomeration.

Predecessors of the comic strip date back as far as the 13th century. They include 17th- and 18th-century printed broadsheets featuring both religious and profane images and 19th-century humor magazines such as *Puck* (1876) and *Judge* (1887), which printed several political and social cartoons in each issue. However, the recognizable elements of the modern comic strip did not fully emerge until the 1890s and were fueled by the newspaper syndication wars fought by William Randolph Hearst and Joseph Pulitzer. Recognizable elements included recurring characters, dialogue balloons, and sequential art. Earlier comic illustrations typically were only one panel, with an accompanying script below or adjacent to the image,



This 12-frame comic strip shows Buster Brown and his dog Tige inspired by the sight of a group of Boy Scouts drilling with rifles and flags. Buster and Tige sign up with a recruiter, who gives Buster a list of rules—in particular, the command, "Always respect your elders." That night, Buster is awakened by a man wearing a false beard and carrying a pistol, who tells Buster to show him where the valuables are kept. In line with his resolution to respect elders, Buster shows him the safe. Later, his horrified mother informs him that the man was a burglar. Buster reflects that, after all, "Soldiers are not kind to their elders." The strip concludes with a long "resolution" in which Buster resolves to do what he can to show his devotion to his country. Richard F. Outcault originated the Buster Brown strip in the *New York Herald* in 1902, but in 1905, he was lured away by William Randolph Hearst and moved the strip to the *New York American.* The Boy Scouts in this sequence are probably members of one of the rival, more militaristic groups of Boy Scouts that flourished briefly in the second decade of the 20th century.

and rarely featured the same cast of characters from one issue to the next.

In the last quarter of the 19th century, new communication and transportation technologies, cheaper printing techniques, and a growing, increasingly literate urban population contributed to the emergence of inexpensive daily newspapers such as Hearst's *New York Journal* (1895) and Pulitzer's *New York World* (1883). These newspapers catered to a middle- and lower-class readership, delivering daily dosages of murder, lurid scandal, and comic strips. Comic strips featuring recurring characters were seen as a viable strategy for getting return readers and establishing a form of brand identification with particular newspapers through the personalities of the comic strip characters. Mass immigration and an uneven literacy level among readers made the "funnies" even more marketable, drawing in constituencies that might otherwise spend their increased leisure time and disposable income elsewhere. As the Hearst and Pulitzer newspaper empires grew beyond New York, they began to syndicate local strips across the nation, selling them to their own newspapers as well as to papers in cities in which they did not yet have a foothold. In this manner, many early comic-strip characters achieved national iconic status.

Among the most popular early comic-strip characters were the Yellow Kid (1895) and Buster Brown (1902). Both were created by Richard Outcault. Also popular were Rudolph Dirks's Katzenjammer Kids (1897). Although Outcault's and Dirks's strips featured the adventures and high jinks of precocious children, Ian Gordon and others have argued that these characters appealed more to adult readers than they did to children (although they were read by many children as well). Gordon asserts that the appeal of many early comic strips lay in their ability to negotiate tensions resulting from the onset of mass culture, even as the strips themselves were products that profited from that same milieu. In this manner, comic strips drew upon ambivalences in "modernist sensibilities" by using the bad behavior and "innocent" insights of their child characters to poke fun at consumer culture and to allow adult readers to vicariously rebel against its constraints through their refusal to conform to the rules. At the same time, their appeal led to increased newspaper sales and their replication (sometimes legally licensed, often not) in a wide array of consumer products.

In particular, Buster Brown's appeal drew upon the dichotomy between his physical appearance and style of dress, reminiscent of Victorian-era representations of childhood innocence, and his repeated transgressions and pranks at the expense of his parents and other adults. Although Buster was often punished for his actions at the end of each strip, temporarily restoring order, readers were assured that this would not stop him from breaking the rules again the next day.

In part, Buster Brown's comeuppance at the close of many strips was a response to an increasing concern that the bad behavior in comic strips was further evidence of the decay in moral values brought about by the very processes of mass culture and consumerism that strips sought to exploit and unravel. Although adults enjoyed the transgressions found in these strips, they often deflected their ambivalence toward mass culture by expressing concern that these same comics aroused too much excitement in children, encouraged bad behavior, and were a poor substitute for more wholesome forms of entertainment.

William Donahey, creator of a child-friendly, single-panel comic called *The Teenie Weenies* (1917), attempted (with mixed success) to exploit the wholesomeness of his creations through his marketing and licensing efforts while also justifying their commodity status by emphasizing their ability to teach children good moral values. Buster Brown became the first brand-name character in U.S. history and was heavily licensed by Outcault across a wide range of products, including shoes, candies, toys, clothing, plays, films, and many other forms of ephemera. Unlike Donahey, Outcault purposely marketed the contradictory innocence and mischievousness of his creation.

In the 1930s, a new type of strip began to replace the gag-focused, episodic comic. This was the continuity strip, whose most popular subgenre, the serialized adventure strip, ended each day with a cliffhanger that left its hero in mortal peril. Although these strips were met with even greater concern by those bemoaning the negative effects of consumer culture on children, the adventure serial is considered by many comic strip historians to be the pinnacle of the medium's artistic and narrative potential, imaginatively combining the fantastic and the authentic, the cartoonish and the realistic in their imagery and plots. While some adventure serials, such as *Wash Tubbs* (Roy Crane, 1924) and *Terry and the Pirates* (Milton Caniff, 1934) featured teenage adventurers, most had adult heroes (*Flash Gordon* [Alex Raymond, 1934], *Dick Tracy* [Chester Gould, 1931], *Prince Valiant* [Harold Foster, 1937]) who served as wish-fulfillment fantasies for adult and child

readers alike, depicting exhilarating, if impossible, worlds filled with treasure hunting and crime fighting that countered the monotonous and often-unrewarding demands and expectations of a Fordist labor economy.

Many of these strips reached the height of their popularity during World War II, sending their heroes off to fight Axis enemies while promoting patriotism, encouraging enlistment, and selling war bonds in the strips and in other forms of public service publicity coordinated through the Office of War Information. In 1943, a speech given to teenage enlistee Terry before he heads out to fight the Japanese enemy appeared in a Sunday strip of *Terry and the Pirates* and was dubbed "The Pilot's Creed." It was read into the Congressional Record and distributed to military personnel for years to come.

World War II also contributed to the demise of the adventure serial, as paper shortages reduced the amount of space newspapers could devote to comic strips. Rather than cancel the strips, most papers reduced them in size, cutting five columns down to four, full-page strips down to half-pages, and cropping the bottom of each strip by as much as 25% to cram more in. These changes were not conducive to the style of art most adventure serials employed. By 1950, the gag strip once again became the most prominent form of comic strip and has remained so to this day.

The 1950s also saw the debut of three comic strips that would greatly influence American popular culture and the cartooning industry for decades to come: Charles Schultz's *Peanuts* (1950), Hank Ketchum's *Dennis the Menace* (1951), and Mort Walker's *Beetle Bailey* (1950). All three drew upon aspects of children and youth culture to comment on the era's suburban idealism and conformist pressures, albeit from somewhat different stances.

Peanuts has been described by Robert Harvey as a strip about "introspective li'l folks" (Harvey, 1998). It relied for its humor on the decidedly adultlike sensibilities and concerns of its child characters, establishing the uses of non-sequitur humor as the norm for comic strips to this day (particularly those featuring children and animals). Through this dichotomy, Schultz was able to poke gentle fun at emerging fads like pop psychology (Lucy's infamous booth that offered therapy for the price of a nickel led Charlie Brown astray on most occasions) and pseudointellectualism (often exposed through Snoopy's aspirations to become the first canine novelist).

Dennis the Menace was launched by Ketchum against advice that strips featuring children were outdated. The strip was an instant success. In many ways, Dennis was a throwback to the mischievous child strips like *The Yellow Kid, The Katzenjammer Kids,* and *Buster Brown*. Unlike the Victorian values Buster repeatedly failed to live up to or the lower-class immigrant narratives played out in the Yellow Kid and the Katzenjammer adventures, however, Dennis the Menace was positioned from the onset as an all-American, middle-class kid whose pranks and troublemaking rarely pointed to contradictions or anxieties bubbling underneath the surface of suburbia but instead often reinforced the wholesomeness of white middle-class mores, transforming pranks from dissent to innocent play.

Beetle Bailey was the most political of the three strips, originally portraying Beetle as a lazy, anti-authoritarian college student, and then, once the Korean War broke out, enlisting him in the army, where his own efforts to shirk responsibility were equaled only by the incompetence of the military machine.

These strips, as well as those that followed them, were also highly merchandised through a long line of licensed products bearing their images, marketed to children and adults alike. In addition, their characters were licensed as spokespersons for various marketing campaigns. Efforts to maintain the childlike innocence of their "stars" while simultaneously profiting from these same attributes were often at the forefront of concerns on how best to sell comic-strip characters. Epitomizing such tensions is a January 31, 1968, letter from Ketchum to Sandy McGowan of the Dancer-Fitzgerald-Sample advertising agency regarding commercial spots for A&W Restaurants that featured Dennis as the spokesman. Ketchum wrote that Dennis was not a "a little pitchman. He's merely the dirty-faced kid next door who couldn't care less about saving nickels or even where he gets his next root beer."

Comic strips depicting children have also come under attack for their political satire. Although the exploration of political concerns in comic strips is often associated with the contemporary moment and strips such as *Doonesbury* (Garry Trudeau, 1970), *Bloom County* (Berke Breathed, 1980), and *The Boondocks* (Aaron McGruder, 1998), in fact they have been a staple of the medium (and the controversy surrounding it) since the 1920s, when Harold Gray's *Little Orphan Annie* was born (1924). Gray is considered an arch-conservative, and his strip overtly pitted Annie's self-reliance and the self-made fortune of her rich benefactor, Daddy Warbucks, against Franklin Roosevelt's New Deal politics. The strip generated a

great deal of furor among readers, many of whom would regularly write letters to the editor arguing that editorials belonged on the editorial page and that the strip contained political propaganda that was harmful to young readers.

Many cartoonists have followed Gray's lead in using children to voice political concerns. In particular, McGruder's *The Boondocks* has provided a voice for African American political concerns through the often-angry, savvy 10-year-old Huey and his gangsta-wannabe 8-year-old brother Riley. McGruder has used the strip to openly attack Republicans, the war in Iraq, and the commodification of African American culture by celebrities such as Mariah Carey and Puffy. In one well-known strip, Huey proclaims, "Jesus Christ was black, Ronald Reagan was the devil, and the government lied about 9/11." Although coming from the opposite side of the political spectrum from Annie, McGruder's strip has faced equally harsh criticism for its use of children as so-called propagandists and on occasion has been pulled from various newspapers because of its content. Much like Annie, Dennis the Menace, and Buster Brown, the Boondocks characters have also successfully been merchandised, with a new series launched in 2005 on the Cartoon Network.

COMIC STRIPS, GENDER STEREOTYPES IN

It has been argued that comic strips represent a shorthand version of reality and most reflect the collective American subconscious. This art form is faithfully read by hundreds of millions of readers each week, regardless of age, sex, class, or race. Thus, it is not surprising that researchers have repeatedly turned to comic strips in an attempt to discern trends in culture. This research by and large has concluded that comic strips generally perpetuate, rather than challenge, gender stereotypes. The media play an important role in the formation of gender identity among children and adolescents, so their exposure to gender stereotypes is of significance in understanding identity development.

Beginning in 1974, research on gender representation in comic strips indicated that traditional sex-role stereotypes predominated in the comics. Ten years later, a replication of the earlier study demonstrated that females continued to appear less frequently and to remain in the home more often than males. They also were likely to be portrayed in stereotypical roles, engaging in child-care and home-centered activities. A similar study published at about that same time concurred; men were represented far out of proportion to their true ratio, and women were represented far less than their true proportion of the population. In comic strips, female characters were much less likely to work outside the home than women in real life. Men were rarely shown involved in child care or the home. This builds on research that indicates that single men are presented as autonomous and in control of their lives, but married men become meek and defenseless against their wives.

Other research conducted in the mid-1980s uncovered the "double burden" of the working woman in comics. This line of research compared traditional and modern comic households, finding that, although the appearance of husbands exceeded that of wives in traditional comics, the opposite was true in modern comics. Husbands and wives in modern comics were more equally represented in indoor settings versus outdoor ones, whereas traditional comics showed

men outside and women inside. Surprisingly, modern working women spent more time on household tasks and child care than did traditional wives. None of the cartoons showed a husband cleaning, doing dishes, preparing meals, or doing laundry. Men did, however, do yard work and home maintenance. Working women were portrayed negatively, spending less time with their spouses, being “hard,” controlling, critical, and castrating toward males, and experiencing much stress. The working woman was in other ways portrayed as superwoman, doing it all. Regardless of whether the woman works, she is primarily responsible for household tasks and childcare and can expect little help from the husband. The home lives of families without working moms are portrayed as happier; when the mom works, home life is disrupted.

Another line of research has focused more particularly on the representation of fatherhood in comic strips. This work has emphasized the degree to which fathers, as compared with mothers, have been portrayed as incompetent, nurturant, or supportive, and the degree to which mothers, as compared with fathers, are mocked or made fun of in comic strips. Such inquiry is based on the assumption that the level of incompetence portrayed can be used as a barometer of social trends. Early research in this area examined *Saturday Evening Post* cartoons published between 1922 and 1978, finding that fathers were likely to be portrayed as incompetent until the 1970s, when portrayals improved. Building on this study, follow-up research broke down various eras more specifically. This study found that fathers were depicted as less competent during the 1920s, but the disparity between males and females in terms of incompetence decreased in the 1930s and even more in the early 1940s. Looking at comic strips on Mother’s Day and Father’s Day, research indicated that an improved image of fatherhood appeared in the 1980s and continued into the 1990s but not at the expense of the presentation of women. This study also found that fathers in the 1960s were more likely than in the past to be portrayed as supportive and nurturant but also were more likely to be mocked. Discrepancies between males and females in terms of warmth decreased from the 1950s to the 1960s not because men became more nurturant but because women became less so.

Analysis has also focused on comparison of the treatment of male and female adults and children, especially in single-income homes versus dual-income homes. Fathers and sons are pictured more frequently in traditional single-income families, and mothers and daughters are shown more in dual-income, modern cartoons. Sons in single-income homes and daughters in dual-income homes were more likely to be pictured outside the home than their opposite-sex counterparts. The comics show that maternal employment has a greater impact on sons than on daughters, although both male and female children are more likely to share in household responsibilities and show disciplinary problems if the mom works outside the home. The cartoons generally show stereotypical images of male and female children. Regardless of whether the mothers work, they tend to interact with the children more, and more positively than the fathers, who are more disciplinary and threatening. Sons are disciplined more frequently than daughters. When fathers interact with a child, it is more likely to be with a son than a daughter.

In the most recent study of gender in the comics, stereotypes were labeled a “time-honored tradition.” In 2004, women were still underrepresented, more likely to be married and to have children, and less likely to have jobs. Females did domestic work, and males did yard work. Females were more aggressive verbally. Minorities were almost nonexistent.

COMMERCIAL TELEVISION AND RADIO IN SCHOOLS

Commercial television and commercial radio came into schools notably later than advertising and marketing

into media in general. Whereas the marketing trend began in the early 1920s, commercial television did not enter schools until 1979. In that year, Los Angeles-based Channel One first operated in public school classrooms. Commercial radio made its entry into schools in 1992 with Minneapolis-based Star Broadcasting. Although very little impact research exists regarding the effect of Channel One and Star Broadcasting upon children's consumer attitudes and behavior, early research conducted on Channel One points to a significant product-advertising impact in schools.

CHANNEL ONE

Since 1979, Channel One has operated in schools under a contractual agreement with a participating school whereby the school agrees to show the Channel One news program (10 minutes of news and 2 minutes of commercials) on 90% of all school days in 80% of all classrooms. In return, the school receives a satellite dish installed by Channel One, two central videocassette recorders, internal wiring for transmission throughout the school, and a 19-inch television set for each classroom. The daily news program feed is beamed from Los Angeles to the school's satellite dish between 3:30 and 5:30 p.m. Other program and channel offerings also are beamed to the school for review and classroom use at the discretion of individual classroom teachers. The "golden goose" is the daily news program and its paid commercials for products ranging from candy, pretzels, gum, and soft drinks, to snack foods, fashion apparel, and athletic shoes. Viewing the daily news program is contractually mandated. Because Channel One has the unique capacity to reach all of the given child and adolescent target market in one setting, Channel One is able to charge premium rates for its ad space, and advertisers, who are readily aware of the unique setting and opportunity, are quite willing to pay. All equipment is owned, operated, and maintained by Channel One.

STAR BROADCASTING

Star Broadcasting markets to both public schools and military installations. In its radio operations in schools, Star Broadcasting follows a contractual arrangement similar to Channel One's and provides a satellite dish, wiring, and speakers. Star Broadcasting then beams Top 50 "hot rock" or "hot country" music and ads into the school's hallways, lobbies, and lunchrooms. The experience is comparable to listening to any mainstream commercial rock or country music radio station. For carrying the service, Star Broadcasting pays cash to the schools—a payment roughly equal to the revenue Star receives for carrying one single ad on one single day.

CONTRACTUAL PREVALENCE IN SCHOOLS

Figures on prevalence are proprietary and difficult to obtain. Both Channel One and Star Broadcasting target middle and high schools. By the company's own statements, Channel One has a contractual presence in roughly 38% of all U.S. middle and high schools and expects to add 1,000 schools per year over the next several years. Star Broadcasting reports presence in 400 schools nationwide.

STAKEHOLDER PERSPECTIVES ON PRACTICE AND PREVALENCE

Three basic forces drive commercialism in schools. First, because tax dollars have not kept pace with school expenses, and because the general public resists tax increases, school systems are hungry for dollars. Second, corporations such as Channel One and Star Broadcasting recognize the uniqueness of this venue for product placement targeting their markets, and they readily pay cash and provide equipment in exchange for the opportunity to do so. For their corporate clients, it is much more cost-effective than trying to reach smaller fractions or segments of their target group in non-school-based venues. Third, students are entry-level consumers. The brand preferences and consumer patterns they form now are likely to be brand and company loyalty patterns that will continue throughout their consumer lives. Taken together, these driving forces provide a financial opportunity for schools and their corporate partners alike.

The broader potential costs of these practices are weighed most heavily by portions of the public and by consumer groups, who have raised the basic question of what education should and should not be. Critics of these advertising practices claim that the classroom and its hallways, lunchrooms, and lobbies should be advertising- and marketing-free zones. Those who take this position believe that parents deserve the assurance that school is a setting in which education is the only goal and that children and teens will not be courted by advertisers and targeted by marketing.

Critics also feel that the school and classroom settings compound the impact of marketing practices by tacitly implying that these ads and products have the endorsement of the school and its teachers. Because these criticisms concern children's health and vulnerability, these voices draw broadly from the medical community, educators, consumer groups, parents, and even students themselves.

IMPACT RESEARCH

Very little impact research exists regarding the effect of Channel One and Star Broadcasting upon children's consumer attitudes and behavior, and the scant research that does exist focuses solely on Channel One. In 1993, Bradley Greenberg and Jeffrey E. Brand examined the impact of Channel One on 10th-grade viewers. When students from two high schools receiving Channel One were compared with a matched group of students from two high schools not receiving it (the control group), the impact of Channel One's advertising surfaced in several ways. First, compared to the non–Channel One students, the viewing students expressed significantly more favorable attitudes toward the five most heavily advertised products. Second, when asked to name the brand they would purchase in each of eight product categories, the Channel One students named significantly more program-advertised brands than did the nonviewing students. Third, the Channel One students scored significantly higher than nonviewing students on a scale measuring materialistic attitudes (e.g., statements such as "Most people who have a lot of money are happier than most people who have only a little money."). There is much more to be investigated, but these results clearly suggest that commercial broadcasting in schools does have an impact on children and adolescents.

COMMERCIAL TELEVISION IN SCHOOLS: CHANNEL ONE

Traditionally, there have been links between business and education in the United States, and examples of this connection are well-documented. However, according to a General Accounting Office (GAO) report, commercial activities in American schools have been increasingly visible in recent years. One such commercial activity is commercial television. Historically, teachers have rarely used television in schools, but the appearance of Channel One in classrooms in 1989 signaled a departure from this precedent. Despite controversies, Channel One programming is now shown in schools across the country. According to Channel One, 8 million students in 12,000 middle and high schools in the United States now have access to its programs. However, the future of Channel One, and commercial television in schools in general, is uncertain. The debate surrounding this issue will no doubt continue.

Channel One was launched as a pilot venture in March 1989 by magazine entrepreneur Chris Whittle. In return for showing a 12-minute current events program, which included 2 minutes of commercials, to students in their classrooms, each participating schools received a satellite dish so that the show could be received, a control console, and televisions for classrooms. The program was tested in six schools and deemed a success by Whittle. Channel One was then launched in March 1990 in 400 middle and high schools, and by the end of the 1990, 5,000 schools were signed on to participate. In 1994, Primedia, Inc. (then K-III) purchased Channel One from Whittle Communications.

However, Channel One has been criticized by many education groups, parents, school boards, and magazine and newspaper editorial writers. In fact, in June 1989, the New York Board of Regents banned Channel One from all New York public schools. The

board adopted another regulation in February 1990 prohibiting schools from entering into contracts that compelled children to view television advertisements, although Whittle lobbied heavily to allow Channel One in New York.

Channel One was also banned by the State Board of Education in North Carolina in 1990. When Whittle ignored the ban and signed a contract with the Thomasville, North Carolina, Board of Education, the state board sued. The case went to the North Carolina Supreme Court, which decided in Whittle's favor, ruling that the decision to show Channel One should be left to local school boards. The same argument was used by the Texas Board of Education in 1992 when it refused to ban the program.

In June 1990, Bill Honig, California's state superintendent of public instruction, launched an ad campaign protesting Channel One in order to push the legislature to ban Channel One and to discourage potential advertisers. Honig also promised to withhold state funds for the time that students spent watching commercials during the program. According to the *Wall Street Journal,* Whittle spent more than $1 million on lobbying in California by August 1993, and he was able to defeat three attempts to regulate Channel One in California. In September 1992, however, the California Superior Court ruled that Channel One could be shown in California schools, but it also held that teachers could decide not to show it, that school districts were required to provide alternative activities for students if their teachers decided not to show the program, and that parents had to be informed that their children did not have to watch the program.

More controversy came in 1994, when Karen Miller, a parent, requested a list from the Texas Education Association of all schools using Channel One. The agency refused, claiming that it had signed a nondisclosure agreement with Channel One when it had obtained the list. Channel One, however, decided not to enforce its agreement, and the list was given to Miller. It was found that Channel One had not paid the Texas business personal property tax, and in 1995 Channel One was required to pay $2 million in back taxes and penalties.

In May 1999, the topic of Channel One was discussed in a hearing before the Senate Health, Education, Labor, and Pensions Committee. Senator Richard Shelby, an Alabama Republican, had long lobbied for the hearing. Consumer advocate Ralph Nader and conservative activist Phyllis Schlafly denounced Channel One.

DirecTV is another example of commercial television in schools. In May 2001, DirecTV announced that it would give free educational programming to up to 50,000 schools in a venture called the "school choice package." DirecTV would also provide 12,000 low-income schools with the necessary equipment to view the programming. Most of the channels included in the school choice program contain advertising.

In 1999, a Canadian firm, Athena Educational Partners, introduced the Youth News Network (YNN), a 12-1/2-minute program similar to Channel One's. YNN has sparked the same criticisms and opposition as Channel One.

COMPUTER-MEDIATED COMMUNICATION (CMC)

Computer-mediated communication (CMC) refers to human-human interaction via the computer. Some of the popular applications of CMC are email, instant messaging (IM), chat rooms, bulletin boards, and newsgroups. Compared to face-to-face (FtF) communication, CMC liberates communicators from the need to be physically co-present and thus from the consequent influence of nonverbal cues. Although some theorists and researchers argue that CMC-based relationships cannot be as rich as those formed in FtF encounters, others have identified ways in which CMC can actually increase intimacy among users. Research has offered growing evidence that CMC can enhance the lives of youth and adolescents in a variety of ways, including strengthening their communication skills, helping them to build interpersonal relationships, and helping them find information and peer support related to health issues.

THEORETICAL PERSPECTIVES

A central question about CMC is one of communicative richness: Is CMC as effective as FtF in fostering communication and building relationships between people? Scholars have debated the answer to this question since the early days of computing. Those espousing the *relationship-lost perspective* argue that CMC-based relationships are necessarily impersonal because of the absence of many features considered important by conventional theories of relationship development—nonverbal features (e.g., tone of voice, facial expressions, gestures) and potentially influential interpersonal features (e.g., physical attractiveness, skin color, gender). Meaning, usually aided by the use of nonverbal cues, is more likely to be misunderstood and unclear. According to uncertainty reduction theory, the diminished ability of CMC to reduce uncertainty stops, or at least slows down, the development of interpersonal relationships. The relative lack of social cues serves to exacerbate this difficulty in reducing uncertainty. Theories of relational development highlight the importance of physical appearance and physical attraction, especially in the development of romantic relationships. Yet such information is usually unavailable in CMC settings. According to social presence theory, social presence is a communicator's subjective sense of the salience of an interaction partner. It includes a set of cues that a medium offers: verbal, visual, and their subcategories. The fewer the cues, the less the degree of social presence one experiences when using that medium. Based on this theory, users feel less social presence through CMC. Social context cues theory also supports the relationship-lost view by showing that the decline in contextual, visual, and aural cues leads to decreased awareness and sensitivity, causing CMC to be more impersonal than FtF communication.

The *relationship-liberated perspective* poses a direct challenge to this position. Joseph Walther's social information processing theory, which represents one alternative to social presence theory, suggests that, because people need to manage uncertainty and develop relationships, they will adapt the textual cues to meet their needs when faced with a channel that does not carry visual and aural cues. Walther illustrates that, over time, email provides no fewer opportunities for positive personal relationships than FtF communication. It is not that CMC cannot convey relational messages; it simply needs more time to do so. Three factors that influence interpersonal relationships within CMC are presented in social information processing theory. First, people are naturally motivated to make friends with others (*relational motivators*). Second, over time CMC users develop the skills to decode textual cues to form interpersonal impressions. One example of this is the use of *emoticons*, such as ":-)" to indicate a smile. Through emoticons, some limitations of CMC may be overcome. Third, individuals who communicate through these technologies adapt strategies for attaining psychological-level knowledge within this new environment. For example, interrogation, self-disclosure, and deception detection are developed to function without contextual or nonverbal cues. Therefore, individuals are able to form impressions, gain interpersonal knowledge, and develop relationships solely through textual interaction. However, the dimension of time is critical to our understanding of relationship development through CMC. The domain of social presence is limited to short-term interactions only. When communication is expanded beyond the short term, CMC achieves normal interpersonal levels. At this point, the presence of social cues can even become an obstacle. Although the relationship-lost perspective of CMC might argue that anonymity

decreases attraction to group members because of the lack of interpersonal cues, a further study by Walther and his colleagues indicates that in new, unacquainted virtual teams, seeing one's partner promotes affection and social attraction, but in long-term online groups, the realistic images dampen the affinity.

Judee K. Burgoon and her colleagues examined three structural features (mediation, proximity, and modality and context richness) that have particular relevance for the presentation of verbal and nonverbal cues in human interaction. They found that mediation, distance, and reduction in some nonverbal channels did not diminish actual decision quality or influence and in some cases actually promoted performance.

REDUCED SOCIAL CUES, ANONYMITY, AND PERSONAL INTIMACY

Therefore, contrary to common sense, the reduced social cues and anonymity of CMC can actually promote intimacy among users. The hyperpersonal model of CMC proposed by Walther states that CMC is sometimes even friendlier and more social than FtF communication. In CMC, users have the opportunity for selective self-presentation and can choose the positive aspects. The reduced social cues in CMC can lead to an idealized perception by the perceiver. The ability to express emotions in text and self-presentation is very important for a social and friendly atmosphere and can lead to the development of friendships. The hyperpersonal communication framework offers an approach to understanding ways in which CMC can be richer than parallel FtF activities. Yifeng Hu and her colleagues conducted a survey of American college students who used IM. Their research showed a positive relationship between amount of IM use and perceived verbal, affective, and social intimacy between friends. This suggests that IM between acquaintances promotes rather than hinders intimacy. Moreover, this study found that frequent conversations via IM actually encourage the desire to meet face to face. Even among strangers, the anonymity of CMC and text-based interaction promotes intimacy. An earlier CMC study by Hu on romantic relationships among Hong Kong college students using IM revealed that lack of social cues decreases evaluation apprehension, thus promoting worry-free self-presentation that allows for a more accurate communication of meaning through text.

REDUCED SOCIAL CUES, ANONYMITY, AND GROUP IDENTITY

The social identity model of deindividuation effects (SIDE) proposes that, when social cues are scarce and relevant social identities are known and salient in the context of the interaction, group characteristics will be attributed to individuals. Thus, the lack of social cues in CMC can accentuate the unity of the group and cause persons to be perceived as group members rather than as distinctive individuals. Anonymity actually promotes a shift in the kind of self-awareness from the personal to the group self, rather than a loss of self-awareness; that is, individuals tend to identify more as group members rather than as individuals.

IMPLICATIONS FOR CHILDREN AND ADOLESCENTS

Given the widespread use of CMC technologies by children and adolescents, the social psychological effects of CMC have implications for the nature and course of mediated interpersonal communication and organizational communication at all levels, from maintaining friendships to developing intimate relationships, from building one's social network to performing community or other group-level activities.

Research by Brian Murfin suggests that CMC has the potential to foster the development of social and communication skills and abstract thinking for middle school students. The report from the Pew Internet & American Life Project reveals that teenagers' use of the Internet plays a major role in their relationships with their friends, their families, and their schools. Teens generally think that CMC enhances their social life and academic work. They are generally intense users of IM, using it and other online spaces and tools to play with and manage their online identities.

IM, one of the applications of CMC, has been especially popular among adolescents. The first online behavior survey among youth in Hong Kong, conducted in 1997 by Breakthrough, a nonprofit youth organization offering cultural, educational, and service activities to young people in Hong Kong, showed that 75% of teens participated in "instant online communication" activities, among which nearly 70% said they had made friends through the Internet. Two years later, another survey taken by Breakthrough showed that 50% of the middle and high school students used IM as their communication

tool. IM not only strengthened the bond among young people but also became a channel for making new friends. In addition, IM was regarded as a space for free speech and expression of self.

Another area of CMC research on children focuses on learning disabilities. A project undertaken by Elizabeth Keating and Gene Mirus suggested that computer-mediated videotelephone interactions can significantly improve the educational experience of deaf students, who are often cut off in classrooms with hearing students. CMC can permit them to participate in peer activities with other deaf students at other sites via video conference, forming a virtual deaf community.

CMC research is increasingly relevant in the area of online health communication as well. A review by Joseph Walther and Shawn Boyd shows that users of CMC settings in online health sites appreciate the informational and emotional support received from those groups, and find those groups attractive not just because there is no time pressure or geographical boundary but because it provides convenient access, multiple perspectives, anonymity, lack of judgment, ease of locating peers who share the same (rare) disease, and a sense of community and similarity, among other advantages. Modern CMC technologies allow for deliberate and judicious use of social cues, affording users an increased universe of decision making relating to self-presentation and impression management. All of this is likely to enhance adolescents' ability to communicate, both textually and through other modalities.

COMPUTER USE, AGE DIFFERENCES IN

The majority of American children, even those of preschool age, are using computers. Nearly all 8-to-18-year-olds and almost half those age 6 and under have used a computer. When the word *computer* is mentioned, desktop and laptop computers immediately come to mind, but youth increasingly have

access to handheld devices such as cell phones and personal digital assistants (PDAs), which do much of what a traditional computer does and sometimes more. Additionally, computer use today is almost (though not completely) synonymous with "going online." This entry covers both online and general use of desktop and laptop computers.

PREVALENCE OF COMPUTER USE BY AGE

Computer use increases steadily with age. Thirty-one percent of 0-to-3-year-olds, 70% of 4-to-6-year-olds, and 98% of 8-to-18-year-olds have used a computer. A combination of studies give a picture of the number of young people, by age, who use a computer on a typical day. About 18% of 0-to-6-year-olds, 38% of 5-to-7-year-olds, and 62% of 8-to-18-year-olds are computer users. Once a child turns 8, there is little difference in children of different ages in terms of how many use a computer on a typical day (59% of 8-to-10-year-olds, 62% of 11-to-14-year-olds, and 65% of 15-to-18-year-olds). However, when looking only at computer use for recreation (for games, instant messaging or IM, surfing the World Wide Web, etc.), we find that teens (11-to-14-year-olds and 15-to-18-year-olds) are more likely to use a computer on a typical day than are tweens (8-to-10-year-olds). Similarly, the proportion of youth who go online for recreation on a typical day increases with age as well. Additionally, some studies find that older wired teens (15-to-17-year-olds) are likely to go online more frequently than their younger peers.

It is important to note that computer ownership increases with age and that young people with a computer at home are far more likely to use a computer on a given day than those without a computer at home. Computer ownership compounds the increases by age in likelihood of computer use.

As a child's age increases, so too does the amount of time spent on a computer and on the Internet. Eight-to-ten-year-olds spend about 37 minutes a day on the computer for fun (excluding schoolwork), 11-to-14-year-olds spend just over an hour a day, and 15-to-18-year-olds devote an hour and 20 minutes daily. Children under 6 years spend an average of 10 minutes a day on the computer. The pattern of daily time spent online for fun follows the same pattern as for recreational computer use: 8-to-10-year-olds spend an average of 25 minutes a day online for fun, 11-to-14-year-olds spend almost 50 minutes, and 15-to-18-year-olds spend about an hour and 6 minutes. This increase in computer and Internet use with age is in direct contrast to the general decline in television viewing with age. (Reported average times spent on various computer activities throughout this piece include those who did not use a computer. The Kaiser Foundation's *Generation M* report by Roberts, Foehr, and Rideout provides more information on patterns of computer use.)

SPECIFIC COMPUTER ACTIVITIES BY AGE

Although computer use increases with age, activities change as children grow up. Computer games, for example, are the recreational computer activity to which the most time is devoted. Younger children, tweens, and young teens are the most avid gamers, with interest and attention waning as children move into later adolescence. Young teens are more likely to play games than older teens, but the average time spent playing computer games does not vary substantially.

Communication is one of the most important computer functions for young people. Whereas interest in computer games decreases with age, interest in IM increases with age. IM, a technology that has existed less than a decade, is one of the most popular uses of the Internet among teenagers. Although only 10% of 8-to-10-year-olds use IM on a typical day, 26% of 11-to-14-year-olds do, and 39% of 15-to-17-year-olds do. The average amount of time devoted to IM increases with age as well, with 8-to-10-year-olds spending an average of 3 minutes a day, 11-to-14-year-olds spending an average of 18 minutes a day, and 15-to-18-year-olds devoting almost half an hour (27 minutes).

Although email is far less popular than faster forms of communication (e.g., IM and text messaging) among young people, likelihood of use of email increases with age. Over a third of 15-to-18-year-olds use email on a typical day, whereas just over a quarter of 11-to-14-year olds do, and just over 1 in 10 8-to-10-year-olds do.

As new technologies have made communication more personal, faster, and more easily accessible, interest in Web-based chat rooms, although never high, seems to be diminishing. Chat rooms are not a popular use of the Internet, and there are no major differences in use by age.

Websites and their related activities, such as shopping and information gathering, garner more attention as young people grow up. The proportion of young people who visit websites on a typical day increases with age: 21% of 8-to-10-year-olds, 34% of 11-to-14-year-olds, and 45% of 15-to-17-year-olds. The average time youngsters devote to websites increase with age as well, with 8-to-10-year-olds spending an average of 8 minutes a day, 11-to-14-year-olds spending 13 minutes, and 15-to-17-year-olds spending 19 minutes.

Computers have become mainstays in young people's media lives, and their importance only increases with age. As adolescents become young adults and enter college, computers surround them, and their proficiency with technology is simply assumed.

COMPUTER USE, GENDER AND

Interactive activities—from computer gaming to instant messaging (IM)—have become a ubiquitous part of youth culture and are popular avenues for education, entertainment, and communication. These technologies, however, are continually evolving, like the experiences of the children who use them. Existing research substantiates that computer behavior patterns for boys and girls have remained stable in some contexts and changed in others. Gender differences are of theoretical interest because young children are thought to develop sex-typed attitudes, preferences, and behaviors through observations of and interactions with the world around them, including the media with which they spend their time.

AN OVERVIEW OF GENDER DIFFERENCES

The research examining gender differences in computing may initially appear inconsistent, with significant works supporting or refuting such differences. Children's media experiences, however, are shaped in important ways over time; thus, gender differences can be more accurately described when considering how computer behaviors, skills, and preferences change as children grow.

Among the youngest of computer users, boys and girls appear to have similar experiences. Sandra Calvert and colleagues analyzed a national sample of parents of children ages 6 months to 6 years and found no significant differences between the computer use habits of boys and girls. The authors suggest newly marketed computer content available to very young children may be equally attractive to both genders. Moreover, in computer interactions, gender differences favoring boys are likely learned over time. From a social learning perspective, children acquire sex-typed behaviors gradually through observation of sex-typed patterns in others. They may also receive approval for "appropriate" sex-typed behaviors and disapproval for "inappropriate" sex-typed behaviors. Therefore, children may internalize sex-role messages

they receive during interactions with computer media, which consequently may affect cognitive, affective, and social development. Those working from the perspective of gender schema theory suggest that personal feelings about characteristics of males and females help individuals choose behaviors that are "appropriate" for their own sex. Particular computer activities may be labeled as "boy" activities, subsequently leading to differential participation levels.

In their 2004 national study *Generation M: Media in the Lives of 8-to-18-Year-Olds,* Donald Roberts and colleagues found that media ownership patterns of boys and girls significantly differed; boys were more likely to own several different personal media. Although the difference was the largest for video games, it was also present for computers and Internet connections. Boys and girls devote similar amounts of time to computer use, but the specific activities of young males and females differ. In general, boys spend more time playing interactive games, and girls spend more time visiting websites, sending emails, and using IM. Uses and gratifications theorists present a functional approach to media use, whereby consumers become gratified by selecting media according to which media characteristics best fulfill their needs and desires. This theory provides a useful framework for explaining sex differences in youth consumption of computer media and online content with respect to individual preferences, personalities, and experiences. The following discussion introduces two of the most common ways that youth use computers: for interactive games and for online behaviors.

INTERACTIVE GAMING

Interactive gaming researchers often do not differentiate among gaming platforms (i.e., games played on computers, video game consoles like Nintendo, or portable devices); moreover, single game titles are frequently available for multiple platforms. A brief overview is presented describing the gender differences surrounding interactive game play that may exist across platforms.

In a 1999 nationally representative study, *Kids and Media @ the New Millennium,* Roberts and colleagues found that gaming was the most common computer use for youth ages 8 to 18. In their subsequent study, *Generation M: Media in the Lives of 8-to-18-Year-Olds*, they found that game playing on the computer continued to account for the most minutes per day (19 minutes) followed by IM (17 minutes) and visiting websites (14 minutes). Moreover, boys were twice as likely as girls to have a video game console in their bedrooms (63% vs. 33%), with similar differences found for handheld gaming devices (63% vs. 48%). Studies of online gaming in particular indicate that males are overwhelmingly the most frequent participants. Historically, boys have consistently reported significantly higher preference for and time commitment to playing computer and video games than girls have, in both home and arcade settings.

Content Preferences

To understand the role of interactive media in the lives of children, it is perhaps more important to gather detailed information about time spent using *particular types* of content, not just an index of total use. Interactive game content varies widely, and media effects are partially dependent on that content. Numerous categorization systems have been developed (e.g., television coding systems, the primary action or main goal of the game, and cognitive demands of the game). Evidence from these studies indicates that boys and girls prefer different types of content, with boys preferring and playing sports games and games containing violence. In a large survey of 900 children grades four through eight, Jeanne Funk and colleagues found that girls were more likely than boys to list educational games as favorites, whereas boys preferred sports games. Girls expressed a stronger preference for games containing cartoon fantasy violence, whereas boys more often preferred games categorized as realistic human violence.

These distinctions in content preferences are critical points for understanding the larger issue of identifying how males and females differ in relating to interactive content and design. Indeed, gender differences are apparent in Web content and design preferences. A study of kindergartners conducted by David Passig and Haya Levin determined that boys spent more time on task and were more adept at computer game navigation than girls. In contrast, girls preferred colorful screens with ample text and moderate, slow-moving animation. Color preferences also differed. Girls were partial to red and yellow; boys preferred blue and green.

Numerous observers have suggested that the predominance of masculine themes (e.g., fighting and war) are the likely explanation for the differential appeal of video game and computer technologies to boys and girls. One might also consider the behaviors

required to win numerous interactive games. Often, playing video and computer games encourages players to repeat cycles of competitive, aggressive behaviors, generally considered undesirable for females. The interactive game "culture" is also a prominent part of boys' socialization experiences. Gaming is a collective leisure activity for boys, and boys' tendency to incorporate computing or gaming into friendship networks may influence use at home and at school. In sum, males continue to lead in the areas of gaming, programming, and computer ownership.

INTERNET AND WORLD WIDE WEB (WWW) USE

The Internet and WWW are increasingly pervasive in the daily routines of children and adolescents. Adolescents invest significant amounts of time downloading music, communicating with friends, shopping for fashions and other consumer goods, researching for school, and seeking news and current events information. They rely on information from computer media to define life and self-identity. A majority of teens use the Internet frequently at home and at school because the appealing audio and visual information available via the Internet provides high levels of multisensory stimulation.

"Early" work assessing Internet and Web behaviors provided a glimpse into the role of the Internet in the lives of young people. A national survey conducted in 2000 by the National School Boards Foundation indicated that boys and girls (ages 2–17) were equally involved in using the Internet, albeit in different ways. Girls were more likely to use the Internet for education, schoolwork, e-mail, and chat rooms, whereas boys were interested in entertainment and games. A related research study in 2000 found significant sex differences for several categories of Internet use by adolescents. Males reported using the Internet more frequently than females for fun, games, music searches, and shopping. Females reported more frequent use for information seeking about colleges and fashion. There were sex differences for online game participation, with boys engaging in this activity more frequently. Moreover, boys positively rated sensational Web content and websites containing game cheats and downloads. Girls, however, positively rated information finding. Sex differences were not present for email, chat rooms, and website visitation. In children, boys and girls reported similar motives for using the Internet.

Most recent studies, including data collected in 2004, indicate that differences between males and females have diminished for overall time spent online. When categorizing types of use, however, a stark contrast continues to exist for interactive gaming typified by male users. Those respective users also significantly exceed the overall online time when compared with other user groups. These findings highlight evidence that gender differences are significant for particular interests and preferences of young media consumers.

Computer-Mediated Communication (CMC)

Instant messaging (AOL, Microsoft Messenger, ICQ) and chat rooms are readily adopted by young media users. In contrast to public CMC, private communication is the primary online activity for adolescents. A 2004 study reported IM as the most popular online activity; the daily average was 40 minutes. Email was also popular. Adolescents generally engage in CMC with those whom they have existing relationships, whereas communication with unknown persons is infrequent. No sex differences were reported for CMC.

Generally, virtual communities are becoming primary sources of social activity. The Internet provides the opportunity to maximize development of virtual communication skills and savvy use of computer media. This illustrates how communication can be successful without face-to-face interactions. Calvert and colleagues found that preadolescent children tend to assume traditional gender roles (i.e., they take on gender roles consistent with their own gender) while communicating in virtual environments. However, the challenge of balancing interpersonal skill development with CMC is evident. With respect to personal development, the Internet and CMC applications provide teens with anonymous platforms for experimentation with social identities. These are opportunities for *role, identity,* and *relationship play.*

IMPLICATIONS OF COMPUTER USE

Early experience with computers has the potential to shape later success in technology-mediated contexts. Childhood is now characterized by early and frequent computer use, preparing children for long-term relationships with computer media. The long-term impact of this early use on development, however, is unclear.

Differential use patterns between boys and girls at young ages may also have important implications. Historically, males have engaged in more frequent use of computer activities when compared to females. Some argue that this can partially be attributed to the mass marketing of computer games to young boys. It has also been suggested that interactive game play has the potential to significantly influence experience with and attitudes toward technology. If such play is an "introduction" to later computer use and computer literacy, boys have an advantage of early experience and comfort with interactive media. Such perceptions or schemas may have detrimental residual effects on females' interest in and use of computer technology. As computer use becomes increasingly ubiquitous across the sexes, some may dismiss the salience of investigations of gender differences in computer behavior. Diminishing sex differences in frequency and categories of use, however, do not translate to similarities of complex cognitive and affective processes in computer-mediated contexts. Instead, empirical investigations of gender differences are warranted and needed to build a comprehensive understanding of the underlying gender structures in human-computer interaction.

COMPUTER USE, INTERNATIONAL

During the 1980s and 1990s, the computer—until then a technology used in offices and production facilities—started its diffusion into private households. In this first phase of the digitalization of private media and communication environments, the computers involved were personal computers that offered a limited range of functions. For children and adolescents, the most attractive uses were for computer games and, far behind that, for educational software. In a second phase, linked with the increasing importance of the Internet and online communication in general, online communication access became possible through home computers. Today, the range of technological options for using digital media content and interactive facilities is much broader; computer technology is integrated into different devices like mobile phones, games consoles, personal digital assistants, and so on. Digital media play an increasingly important part in the lives of children and adolescents, not only as devices for entertainment and education but also as part of the socialization process. To understand the role of computers in the lives of young people, it is necessary to consider the global economic framework within which computer use occurs, as well as the impact of competency gaps and inequalities between countries.

GLOBAL DISTRIBUTION

From a global perspective, ownership of a computer cannot be taken for granted by people in all parts of the world. In 2004, according to a compilation of the International Telecommunication Union within the framework of the "Partnership on Measuring ICT for Development," almost 80% of households in Japan, the Republic of Korea, and Denmark owned at least one

computer; the respective figures were slightly over 70% for the United States, the Netherlands, and Norway. The average in Western Europe was 62%. The latter figure differs substantially from the figure for Eastern European countries (27.5%), which indicates that the distribution of computers is closely linked to economic conditions. This kind of difference becomes even more obvious when looking at countries in Latin America (e.g., for 2003, Brazil, 15%; Peru, 6%), or Africa (e.g., Morocco, 11% for 2005; Ghana, 1% for 2003).

Looking at statistics of computer ownership over time involves the idea of a linear process of diffusion, in which children and young people as well as adults gradually gain contact with computers and computer-mediated communication. According to a mechanistic model, diffusion could be defined in terms of technical equipment with a built-in social or cultural function. Then, the process of diffusion would be just a question of the quantitative distribution of the new equipment. However, building on previous work by Everett Rogers, Friedrich Krotz and Uwe Hasebrink have pointed out that, although new media usually start their diffusion as merely a technological option involving basic hardware and basic software, the matter is more complex. How this option is put into practice and what purposes it is used for are defined by those who use the new tools, by consumer demand, by marketing strategies, by enthusiasts who develop enhanced hardware and software, and by critics who impose certain limitations on development. This collective network of actions gradually leads to a general image of the new technology that includes general expectations about what can and should be done with the new medium. Thus, the diffusion process is a qualitative and constructive process. It is only by this process that a new technological option is culturally and socially defined as a medium. Several researchers, although of different theoretical backgrounds, have emphasized this difference between technological options and culturally and socially contextualized media.

As a consequence, the diffusion of computer technology may follow different qualitative paths in different countries, leading to different definitions of the computer's place and the role it plays in the everyday lives of children and young people. In a comparative survey of European countries, two typical approaches to computer technology have been identified:

- In some countries (e.g., Sweden and Finland), the computer has been introduced by school and other societal institutions. Here, the new medium is constructed according to institutional criteria—as a tool for learning, as something that teachers and parents approve of and that is seen as important for the future in the so-called information society.
- In some other countries (e.g., Germany), the computer has been introduced by private households. Here, the computer use depends on the actual interests and purposes of children; as a result, computers are introduced as games machines, particularly for boys. Parents, who as a rule are rather skeptical about games, may prefer computers to games consoles because computers allow for other applications and thus provide a better opportunity for other purposes to become more important.

Empirical observations indicate that different societies develop specific patterns of access to technological options, a specific range of applications and services, and specific purposes, attitudes, and motivations that underlie the use of computers. As a consequence, one should overcome some oversimplifications typical of much public and political discourse: There is no such thing as "the" computer, and consequently we will not find "the" computer user. The new technological options are culturally and socially transformed into institutional structures and everyday practices. This transformation process takes place according to the specific conditions of cultures, political frameworks, concrete social situations, and individual dispositions. Therefore, the direction and the results of this process may be very different between countries as well as between social groups within and across countries.

Despite all differences between countries, one common characteristic of the diffusion of computer technology is that—because of the high prices—children and young people can decide only to a limited extent whether to buy a new piece of technical equipment. Such media are expensive and, in addition, are rather complicated to use. Thus, when they become interested in new technologies, young people have to rely significantly on their parents or other adults, who usually are themselves not too familiar with the new options and thus might not support the diffusion process even if children are intrinsically motivated to use computers. On the other hand, many politicians, teachers, and even parents strongly emphasize the importance of media education and computer skills. This might create a kind of extrinsic motivation to use new media and as such support

diffusion. As a consequence, whether children or young people become "early adopters" of new media strongly depends on their parents, their schools, and their social and cultural environments.

COMPUTERS AS TOOLS FOR CHILDREN AND ADOLESCENTS

As surveys in different countries show, households with children are more likely to have computers at home, and there is an openness toward new media technologies. One reason for this might be that parents think that computer literacy will be important in enabling their children to cope with challenges at school and at the workplace. Another reason definitely is that many children and adolescents like to deal with computers. One advantage of computers is their multifunctionality; they can be used for very different purposes. As studies in different countries show, playing games is by far the most popular option. Doing some work for school and using educational software are also quite frequent activities; to an increasing extent, so is using the Internet. Due to the improvement of the technology, today's children use their computers also for listening to music and for watching DVDs. An important difference in how boys and girls use the computer is that boys play computer games more often than girls do.

When it comes to the question of how the computer shapes the lives of today's children and adolescents, three arguments seem to be important. First, the role of computers in children's lives is influenced by an *economic perspective.* The introduction and diffusion of digital media are, first of all, an economically motivated process. Politicians in almost all countries view information and communication technologies as top priorities with regard to the future of their respective national economies. With this political support, the paths of diffusion of new media are heavily influenced by an economic model according to which everybody is becoming an individual entrepreneur for her or his own interests, electronically connected within a global cyber-economy. This ideal of the "information society," as outlined in many programmatic documents, has become part of parents' attitudes toward computers and computer-mediated communication and is becoming an increasingly important part of the curricula of educational institutions at all levels.

Second, computers and computer-mediated communication will play an increasingly important role in the process of *socialization.* Children and young people socialize themselves by using computers, particularly by playing games. As Sherry Turkle put it quite early in the diffusion process, the computer is not just a tool for calculations but rather a means to express oneself, to simulate different realities, to experiment with one's ideas. This might widen the range of communicative options and diversity and at the same time support a general trend toward individualization within an electronically mediated global space of communication.

Third, the different paths of new media's diffusion into the everyday lives of young people produce different patterns of *competency gaps and inequalities* between and within cultures and societies. How children and young people realize the new communicative possibilities and develop new communicative skills and social practices depends on several conditions. Investigations of computer access and the kind of computer use show that gender, age, and socioeconomic status are strong influencing factors. In addition, we have noted the drastic differences between the industrialized and less industrialized countries in terms of computer access. Here, the discussion of knowledge and competence gaps and "digital divides" is relevant and may become more and more important in the future. Some evidence suggests that schools can play an important role in providing access to new media, thereby encouraging the development of individual competence in computer use. At the same time, empirical evidence from different countries supports the thesis that, in the future, the relative importance of computer use at home will grow because the school systems do not as yet seem able to keep pace with the development of new hardware and software. Thus, it is unlikely that new media access through schools will reduce existing social inequalities by itself. Therefore, it is a task of governments to create conditions that can help develop cultural practices and competencies related to new media that allow all groups of the population to fulfill their communicative needs, whether or not these can be fulfilled by computer-mediated communication.

COMPUTER USE, RATES OF

For the first time in history, children's use of a medium, in this case the personal computer, has overtaken their parents' usage rates. A study conducted by National Public Radio reports that 44% of America's youth between the ages of 10 and 17 years use a personal computer from home on a daily basis, and 55% of the young people in this age range access a computer at school at least once per week. Additionally, on any given day 42% of children and adolescents from 12 to 17 years access the Internet, according to a study by Lenhart and colleagues.

The amount of time children and adolescents of various age groups are spending with computers on a daily basis is substantial, according to a national study conducted by the Kaiser Family Foundation. Children from 2 to 7 years of age spend an average of 7 minutes per day with a computer. As children get older, they consistently spend more time each day using computers, as children and adolescents from 8 to 18 years old spend approximately a half hour each day with this technology. Although this is a valid average across U.S. homes, usage rates increase substantially when the population of children who have regular access to a computer are specifically considered. On any given day, 65% of young people between the ages of 8 and 18 who have access to a computer in their homes use this technology, whereas only 25% of America's youth without in-home access to computers use them on a daily basis, showing that ease of access clearly impacts those young people who choose to use computers. For only those young people who use a computer daily, the average amount of time spent with the medium is 23 minutes per day for 2-to-7-year-olds and 52 minutes per day for 8-to-18-year-olds. Those children and adolescents who are using computers are spending significant time with the medium.

An important study entitled *Zero to Six: Electronic Media in the Lives of Infants, Toddlers and Preschoolers*, was conducted by the Kaiser Family Foundation and the Children's Digital Media Centers. It is the first national study of media use among the very youngest children, from 6 months to 6 years old. In relation to the computer use, this study found that, on an average day, 27% of 4-to-6-year-olds use a computer, and those who do, spend an average of just over an hour doing so. More than a third (39%) of 4-to-6-year-olds use a computer at least several times each week; 37% of children in this age group can turn the computer on by themselves.

Multiple factors play a role in the access of America's youth to computers and the Internet. Race and ethnicity, parents' education level, and socioeconomic status are the main predictors of children's access to computers in their homes, as demonstrated by the Kaiser Family Foundation's research. Hispanic children spend the least time with computers when compared to African American and white children. Additionally, children whose parents have completed college or some college are significantly more likely to have in-home access to computer than children whose parents who have finished only high school. Moreover, children's access to computers outside of school is directed correlated with higher parental incomes. Although computers have not yet penetrated American households as fully as have other media, such as television and radio, and although many functions of computers are still developing, it is difficult to predict how issues of usage and access are likely to develop in the years of rapid change ahead. This is certainly an area where further research will continue to be needed.

COMPUTER USE, SOCIALIZATION AND

The use of computers and related electronic media forms has skyrocketed in the past decade. Children now communicate via computers with chat rooms, email, instant messaging, and downloaded information that can be passed on. They surf the Internet and play interactive games. They have cell phones, pagers, wireless devices, MP3s, and electronic organizers. According to a Kaiser Family Foundation study released in 2005, 86% of 8-to-18-year-olds had a computer at home, up from 73% 5 years earlier. Thirty-one percent had computers in their bedrooms, up from 21% in 1999. Internet access at home increased from 47% to 74%, and Internet access in children's own bedrooms increased from 10% to 20% in that time period. The number who go online for more than an hour in an average day more than quadrupled, increasing from 5% to 22% in those 5 years.

A major concern for many is whether the increased time spent with computers isolates children or whether computer use can actually foster socialization. The level of use is a critical factor, as there are significant differences between the impact of light-to-moderate use of computers and the impact of heavy use, whether for game playing, communicating with others, or surfing the Internet. There appear to be fewer negative associations with light-to-moderate levels of computer use, especially when a child or adolescent has many other resources and activities that provide other kinds of information about social interactions and social behavior, as well as real-life experiences from which the individual can learn. A child's or adolescent's reason for computer use is also important and is likely to differ between light or moderate users and heavy users.

Many agree that computer use in moderation does not affect children and their social skills negatively and may even increase their socialization. Many children use email to supplement phone and real-life interactions and contacts with family and friends, to communicate with strangers, to meet new people, and even to test various personas. Moreover, some shy children may invite one or two peers over for activity-based interactions, such as playing computer games, and find that their play triggers conversation. In the school setting, although some regret the change that may occur in relationships between students and teachers and among students when computers are used more often, others think that the greater use of computers leads to increased cooperative work and interaction in the classroom.

Although the Internet provides a huge informational advantage, it is also used by many children as entertainment for many hours, most of which are spent in isolation from other family members. Some claim that computer use displaces other family activities, such as talking, playing board games, and reading together, and that it results in less social interaction with individuals outside the family as well. Others have found that time spent on the Internet primarily displaces television viewing rather than other nonmedia activities, such as spending time with friends, playing sports, or doing homework. There are concerns, however, about the discussion groups children use and the relationships they may form anonymously with strangers, especially with the possibility of face-to-face meetings. There is also concern that heavy use of the Internet can lead to depression, loneliness, and isolation.

One cannot assume causal direction, however, when relationships or associations emerge between computer use and reduced time spent with others. Spending inordinate amounts of time on a computer may lead to social isolation and little time with peers and families, but the reverse can also be true. Difficulties within the family or with peers might lead children to avoid those problems or to try to escape difficult situations by spending more time in what they perceive as the relative safety of solitary activities on the computer. That is, spending many hours by oneself at a computer could be a cause or an effect of social problems or other difficulties.

Playing games, whether on a computer or on a portable game system, has become a particularly important part of most children's play and of the social interactions of others. According to the National Institute on Media and the Family and other researchers, video game playing can have both positive and negative social effects. It can provide entertainment and can lead to opportunities for children and adults to play together, and not all games involve high levels of graphic violence. Some games require good cognitive skills and involve complex problem-solving skills and cognitive strategies. On the other hand, some research has suggested that heavy amounts of gameplaying can be associated for some players with social isolation, more aggressive behavior, more exposure to violence and stereotypes, and displacement of other activities, such as reading and

the real-life social interactions involved in playing with friends. Important gender differences exist both in the level of use and in the types of games that are played most often. Boys typically spend more time playing video games, and they more often play action-oriented games, sports, and violent games. Girls tend to play more language-based and puzzle-type games.

As children learn most of their basic social skills such as cooperation, kindness, and effective communication from their real-life interactions and the consequences of those interactions, parental guidance and monitoring are important to ensure a healthy balance between computer-based and real-life social experiences. Longitudinal research is also necessary to assess the long-term effects of computer use on social development and behavior.

COMPUTER USE IN SCHOOLS

The use of computers by school students can be categorized according to five headings: computer-aided learning, information retrieval and processing, design and production, communication, and the study of the computer itself. All these uses can be subsumed, in a general way, under the heading "e-learning." A general theme that runs through all use is the current convergence of computers as information processors and as the successors of older technologies of representation, such as photography, cinema, print, and radio. This convergence is leading to shifts in the curricular use of computers, just as it is leading to wider cultural shifts in society. Although schools often respond positively to new opportunities, they are also often at a loss to know how to respond to new forms of digital culture among young people.

It is difficult to give an accurate general picture of school use of computers because of the economic digital divide, which produces widely different patterns of computer availability and connectivity—not only between the developed and developing worlds but also between different groups within individual countries, and between wealthier and less wealthy European economies, including, for instance, new member states in the European Union. The following descriptions are, therefore, broadly typical of schools in the developed world. However, digital divides exist within these countries too; the digital divide therefore has traditionally been a powerful rationale for providing students with computers to compensate for lack of access at home for children from poorer families. Recent studies show that, in countries where access to computers is lower (such as Italy and Greece), provision of computers in schools is also lower, so the resources available to overcome the digital divide are least available where they are needed most. Finally, this research also points to a different kind of divide: between children's uses of computers at home (driven by social communication, play, and entertainment) and "official" uses of computers in schools (driven by information retrieval). Some argue that this divide reduces real access by alienating children.

COMPUTER-AIDED LEARNING

Computer-aided learning (CAL) covers a wide range of specialized software, which uses computers to present content (through media such as CD-ROM novels, picture books, or textbooks), to teach skills (such as literacy or numeracy), and to alter the nature of classroom presentation (using programs such as PowerPoint or Interactive Whiteboard technology). Key questions about such software are whether a given package improves the nature of learning by, for instance, increasing learner autonomy or making skill acquisition more efficient, or whether it simply replicates older predigital practices, such as "drill 'n' skill" approaches to spelling or arithmetic.

INFORMATION PROCESSING AND RETRIEVAL

Computers are used in this sense in much the same way as they might be in the adult world. Generic tools such as spreadsheets and databases are widely used across the curriculum. The Internet is an increasingly important source of information for students working in all curriculum contexts, although its uses go far beyond information retrieval. The growing rate of broadband access for schools provides an exponential growth of available information in verbal, visual, and moving-image formats. This development also raises questions about what new skills are needed for searching, selecting, and discriminating between information sources.

More specialized software might include graphical calculators in math that represent calculations as visual symbols, computer modeling of an ecological system in science, or digital archives available for an enormous range of subject areas.

COMPUTERS FOR DESIGN AND PRODUCTION

Again, students use computers to design, compose, and make products, texts, and systems in much the same way the adult world does, and they often use industry standard suites for graphic design, Web design, animation, and video. Examples of design work would include computer-aided design and manufacture (CAD/CAM); graphic design work; computer-controlled systems (such as stage lighting systems); student Web pages; digital videos and animations, music compositions, and even student-designed computer games. The purposes of using such software are complex and vary according to the curriculum area. Designs may be created as exercises in aesthetic genres important within subject areas, such as photomontage in art, minimalist compositions in music, or horror films in English and media studies. Alternatively, the purpose may be consolidation of an area of knowledge, as in a student film showing the processes of coastal erosion in geography. Finally, the goal may be to develop an understanding of the design process itself, whether this be principles of graphic or musical composition, of the mechanical control of events in the physical world, or of the grammatical principles of writing or film editing.

The design of new media texts by school students is concomitant with the study and analysis of such texts in media curricula in a number of countries. In this field, the study of "old media," such as film, television, print media, and radio, is changing as these media converge on computer platforms. However, it is fair to say that schools have an uneasy relationship with the cultures of new media, so that the leisure domains represented by digital multichannel television, digital radio, and computer games are frequently regarded with suspicion or even banned outright. On the other hand, there are moves to recognize the importance and value of such uses and cultures, with experiments in the use of personal handheld computers, mobile phone texting, and computer games for the delivery of curricular experiences, to construct playful learning, or even as objects of study.

COMMUNICATION: INTERNET, RESEARCH, EMAIL, INTRANETS

Computers are used for an increasingly diverse range of communication in schools, between students, between students and teachers, and between school and home. Many schools have intranets that provide not only resources and information but also communication options, such as posting homework or consulting teachers. In many schools, students use e-mail to post work or to communicate with friends in exchange projects. Some schools have experimented with videoconferencing for similar purposes. More radically, some schools have explored the value of e-learning with students at a distance from school buildings or other centralized resources. In some cases, this distance learning is a response to geographical factors, such as widely dispersed communities in the Australian bush.

As with forms of representation rooted in the leisure domain and the media cultures of young people, schools have ambivalent relationships with some communication technologies. The growth of global networks on the Internet, as well as local networking and mobile wireless communications (such as mobile phone image sending), has caused some anxiety in schools about their growing inability to monitor, control, and regulate students' communications. At one extreme, this debate has led to rigid forms of control, such as using Internet filter software to prevent students from accessing proscribed sites

and banning chat and instant messaging facilities. At the other extreme, it is argued that young people can learn about Internet risks only through guided experience, that censorship is ineffectual in such a diverse and unpredictable context, and that the answer lies in education rather than protection.

LEARNING ABOUT COMPUTERS

The final use of computers in school involves computers as objects of study in their own right. Students learn aspects of information and communication technology (ICT) that include its ability to structure information, to communicate, to simulate real processes, and to control real objects. This approach to computers as an area of study in their own right leads to accredited courses and programs in higher education.

EFFECTS ON LEARNING

The use of computers in schools has always been guided by the assumption that it will improve learning. However, this assumption has been often untested, driven by government policy and rhetoric rather than research findings. An example is the UK government's rhetoric in the late 1990s about the "information superhighway" and the subsequent implementation of a digital curriculum. When these assumptions are tested against research, the results can be contradictory. A 2003 government review of the research literature in the UK by Cox and colleagues reported generally positive effects of the use of ICT across all curriculum areas. In contrast, a systematic review of international research literature on effects of ICT on literacy by Andrews et al. found no conclusive evidence of positive effects in this area. Primary research in specific applications such as the use of digital video by Reid and colleagues found that the digital medium does provide real learning opportunities but not that teaching and other factors are just as important.

CONSUMER DEVELOPMENT, PHASES OF

Children's consumer behavior has often been studied within the paradigm of consumer socialization. Consumer socialization is the rather effortless process by which children learn the skills, knowledge, and attitudes necessary to function as a consumer. Although there is no single definition of a consumer, most definitions that have been employed seem to entail similar characteristics. A consumer is able (1) to feel and express wants and preferences; (2) to search to fulfill these wants and preferences; (3) to make a choice and a purchase; and (4) to evaluate the product and its alternatives. Research has shown that children of around 12 years of age have all the characteristics of a consumer. From birth, they can express their wants and preferences; by age 2, take actions to satisfy their wants and preferences; by age 5, make a choice and buy products, and by age 8, critically evaluate a product and compare options. Thus, although the consumer behavior of children continues to develop during adolescence, children have become acquainted by age 12 with all aspects of their consumer behavior, at least in a rudimentary form.

FEELING AND EXPRESSING WANTS AND PREFERENCES

Initially, the development of the consumer behavior of children occurs primarily through the interaction between parents, television advertising, and shops. Even from the moment of their birth, children have particular wants and preferences for tastes, smells, colors, and sounds. From this moment, they also begin to communicate their wants and preferences to their parents. However, the expression of wants and preferences is initially primarily reactive: The child indicates when the stimulus offered is pleasant or unpleasant.

SEEKING TO FULFILL WANTS AND PREFERENCES

Once children reach 2 years of age, they begin to express their wants and preferences more actively. During this period, children discover that they have their own wills and begin to experiment with this. Children now begin actively to ask for products they like. This happens particularly when the products are in their direct vicinity, for example in the shop or on television. One study revealed that 16% of the toddlers and preschool children spontaneously asked for one or more products (candies, toys) during a 40-minute video with commercials and children's programs. I don't see this info . . . . The children from the ages of 2 to 3 asked particularly for food, whereas the 3-to-5-year-olds asked for food and toys.

Children can sometimes be very persistent when asking for something. This can lead to some trying situations for parents, for example when they are with their children in a supermarket or toy shop. In one study, 41% of parents of children of 2 years admitted to sometimes having conflicts with their children during shopping. This percentage rose sharply for the age group 2 to 5. With children of 3, some 59% of parents had a conflict at some time, and with children of 5 years of age, this rose to 70% of parents. It was striking how the number of shop conflicts began to decrease at 6 years of age. These results are in line with previous studies, which revealed that parent-child conflict situations in the shop showed a curvilinear pattern.

Why do store conflicts increase during the toddler and preschool phase, and why do they decrease again between the ages of 6 and 8? First, children of 5 to 6 years of age become better able to delay gratifications. Children younger than 6 have hardly any strategies to resist temptations. If they see something attractive, they focus all their attention on the enticing aspects of this stimulus and find it very difficult to resist. Parents can, of course, try to divert their children's attention away from the temptation, but it is only once children reach 5 or 6 years of age that they are able to *independently* use techniques to delay gratification.

The decrease in store conflicts also has to do with the growing ability of children to apply sophisticated persuasion techniques. Studies have shown that very young children quite often ask and whine as well as show anger in order to persuade their parents. Older children, in contrast, tend to use more sophisticated persuasion techniques, such as negotiation, argumentation, "soft-soaping," arousing sympathy, and even white lies.

MAKING CHOICES AND PURCHASES

At 5 years of age, children begin to make purchases independently. The process of choosing and paying for products in the shop initially takes place with the parents there. When children are 5 years old, three fourths have already bought something themselves with the parents present, while one fifth have bought things fairly regularly *without* their parents there. These percentages increase rapidly as the children grow older. By the time they reach 8 years of age, the majority of children have bought something without their parents. At this age, about a half the children already go to the shop regularly to buy things on their own. This is usually a nearby shop or supermarket within safe walking distance.

EVALUATING PRODUCTS AND THEIR ALTERNATIVES

To be able to evaluate products and compare them with alternatives, children need the ability to critically evaluate products on suitability and quality. Various studies have shown that the critical ability of children develops rapidly after around 8 years of age. At that age, every product that they look at is studied in detail and compared with other products. When a child of 8 gets a new pair of sport shoes, each part of the shoe, from the laces to the logo, is carefully examined and compared to the features of other shoes. These older children are also very critical of media products, for example, if they do not look exciting, fun, or trendy. At 8 years of age, children begin to realize that commercials are

made to entice them to buy products. Then, these commercials also no longer escape their critical examination. In contrast to younger children, who primarily see commercials as entertainment, children of this age can be very skeptical about commercials.

CONSUMERISM

Children have long had an active and varied relationship to consumer goods and consumer culture. With the rise of childhood as a distinct modern social category in the West during the 18th century, special goods for children also developed. Early examples include children's literature, children's apparel, and, of course, toys. By the early 20th century, a wider range of children's products were appearing on the market, such as candies, collectibles, child-oriented movies, radio shows, comic books, and the like. Department stores began catering to children not only through product selection but also by constructing special child-themed areas of stores. As the century progressed, children became not only consumers but participants in the ideology and way of life that scholars call *consumerism*. That is, they were adopting a set of values, attitudes, and practices that privilege the acquisition, possession, and use of marketed goods and services.

In the second half of the 20th century, children's involvement in consumer culture continued to grow. In the 1950s, the introduction of television provided an opportunity for child-directed programming and the advertising to fund it. Although a variety of products were represented in the early days of television, toys and sugared cereals were particularly prominent and continue to be important sources of advertising revenue today. Children of this era became swept up in consumer fads, such as the Davy Crockett fad that swept the United States in the 1950s with the airing of Disney's Crockett series.

In the 1980s, the landscape of children's consumer involvement began to change. One factor was the growing purchasing power available to youth, which was driven by rising parental and grandparental monetary transfer to children. Official estimates of this phenomenon are not available, but industry researcher James McNeal estimates that American children aged 4 to 12 made $6.1 billion in purchases in 1989, $23.4 billion in 1997, and $30 billion in 2002, an increase of 400%. The top spending category, a third of the total, is for sweets, snacks, and beverages, followed by toys. Older children aged 12 to 19 accounted for an estimated $170 billion in personal spending in 2002.

In addition, society was undergoing far-reaching changes in ideological attitudes toward children. Authoritarian and patriarchal family patterns of earlier decades were being replaced by far more democratic and egalitarian family styles, and children became far more empowered in household decision making. McNeal estimates that children aged 4 to 12 directly influenced $310 billion of adult purchasing in 2002 and "evoked" another $340 billion, and that the size of this influence market is growing at 20% per year. Influence purchases include a wide variety of food items, restaurant expenditures, vacation destinations and hotels, tourist sites, technology products, children's apparel and toys, leisure expenditures, and even the choice of family vehicle.

Furthermore, in 1997 the average child aged 6 to 12 spent more than 2-1/2 hours a week shopping, a full hour more than in 1981. Children spent as much time shopping as visiting, twice as much time shopping as reading or going to church, five times as much as playing outdoors, and half as much time shopping as playing organized sports. More children go shopping each week (52%) than read (42%), go to church (26%), participate in youth groups (25%), play outdoors (17%), or spend time in household conversation (32%).

A third change was the establishment of child-targeted cable television networks and programming, such as Nickelodeon, Disney, and the Cartoon

Network. This expanded the potential for direct television advertising to children, which until that time had been confined to Saturday- and Sunday-morning television plus the after-school time block. Furthermore, television viewing time increased substantially and remains high, at an estimated daily 3 hours and 51 minutes for children aged 8 to 18 in 2005. A Kaiser Foundation study estimates total media time to be 6 hours and 21 minutes per day. Some researchers have argued that childhood has entered a "postmodern" phase. Advertising has also expanded beyond television to radio, the Internet, public schools, cultural institutions, and everyday life (through peer-to-peer marketing) as advertisers compete intensively to capture children's money, enthusiasm, and loyalty for brands. The volume of marketing and advertising to children rose dramatically, from an estimated $2 billion in 1999 to $12 billion in 2002.

As a result of these trends, children have become far more enmeshed in consumer culture than at any time in history. They are now intensely brand aware, even at ages 2 and 3, and product requests become very heavily brand specific as children age. Youth advertising has shifted from a utilitarian orientation on intrinsic product qualities to highly symbolic messages which emphasize the "sign" value of brands. There has been an intensification of what Robert Goldman and Stephen Papson have called "sign wars," that is, corporate competition centered on images, and an accelerating spiral of changing symbolism. Furthermore, children's products are no longer in their historic location at the bottom of the price-and-quality spectrum but are in a continuous process of upscaling with respect to luxury, status value, and quality. Children increasingly desire and purchase adult versions or styles in categories such as consumer electronics and designer apparel.

Survey data reflect children's growing sense of materialism and concern about consumption. One national survey of found that more than a third of all children aged 9 to 14 would rather spend time buying things than doing almost anything else; more than a third "really like kids that have very special games or clothes;" more than half agree that "when you grow up, the more money you have, the happier you are;" and 62% say that "the only kind of job I want when I grow up is one that gets me a lot of money." A growing body of psychological research finds that adolescents who hold more materialistic values have lower well-being. In one study, children who became more "consumer involved," as measured by a 16-item scale of behaviors and attitudes, were at greater risk for depression, anxiety, self-esteem, psychosomatic complaints, and poorer relations with their primary parent.

CONTRACEPTIVE ADVERTISING

Few would argue that sex does not permeate the media. Research by Dale Kunkel and his colleagues shows not only that the incidence of sexual content on television has risen steadily over the years but also that the media may serve as important sex educators for young people. Yet there are few messages on

television that help children, adolescents, and young adults learn about responsible sexual behavior and sexual health. Until recently, condoms and other contraceptive products were considered forbidden to advertise on television, but they have recently begun to make an appearance.

NETWORK POLICIES

Three of the six broadcast networks as well as numerous cable channels have abandoned longstanding self-regulated policies prohibiting advertisements for contraceptive products on television. Fox was the first network to accept paid condom ads in 1991, with CBS following in 1998 and NBC in 1999. Several channels still prohibit advertising for condoms even though they accept ads for other types of birth control products; for example, ABC, whose channels do run condom commercials, often have restrictions governing times they can be shown and how they may be advertised. Numerous cable channels also accept condom advertisements, including MTV, Comedy Central, CNN, BET, TNT, USA, and TBS.

ABC, WB, and UPN executives continue to bar condom advertising on their networks. UPN aired a condom advertisement for Trojan on one occasion in 1998, but responses from affiliates were so negative that no condom ads have been aired on the network since. The exclusion of condom ads as well as ads for other contraceptive products is still presently enforced, although UPN does broadcast public service announcements (PSAs) discussing HIV/AIDS and awareness of sexually transmitted diseases.

Condoms are not the only form of birth control that continues to encounter difficulties being advertised on television. Blairex Laboratories, the company that manufactures Encare, a vaginal spermicide suppository, attempted to air a commercial that discussed pregnancy prevention on television, but they were rejected by ABC. Fox also refused to air the ad during its prime-time programming schedule on the grounds that, although the network does air condom ads, it does not air products for certain other contraception products or for other products that may be considered controversial. The Encare commercial was finally aired on NBC and CBS, under time restrictions, as well as on the USA Network in 2001.

PUBLIC OPINION

A national survey of 1,142 adults conducted by the Kaiser Family Foundation (KFF) has recently determined that 71% of Americans are in favor of showing condom advertisements on television. Thirty-seven percent of those in favor say that condom ads should be allowed to be shown at any time during the day, and 34% are in favor of airing condom ads only at certain times, such as after 10 p.m., when younger children are less likely to be viewing. One in four Americans still believes that condom ads have no place on television, and such ads have been the subject of criticism by conservative groups from this population.

Americans between the ages of 18 and 49 years old are significantly more likely to be in favor of airing condom ads than are Americans over the age of 50. Among adults under the age of 50, 82% support showing condom ads on television, in comparison to only 60% of respondents over 50. According to this research, more people are opposed to showing beer ads (34%) on television than to showing condom ads (25%).

A test conducted during KFF's research determined that most viewers do not object to seeing condom ads during regular television programming. Advertisements for condoms were rated similarly to the other product ads in this study, such as ads for Allegra (an allergy drug), Toyota Camry, Juno (an Internet service), and Sears. This research also indicates that, even for those who were not in favor of condom ads on television, the viewers did not provide negative assessments of the networks on which the ads were aired, the programs during which they were aired, or the other advertisers whose commercials appeared during the same program.

PUBLIC POLICY

Several factors are responsible for the increasing presence of condom advertisements on television. These include the need to increase HIV/AIDS awareness in the United States since the 1980s, the increasing pervasiveness of sexual content in media programming, the FDA's landmark decision to loosen regulations on advertisements for prescription drugs on TV, and a major $33 million advertising campaign put forth by Johnson and Johnson for their birth control pill Ortho Tri-Cyclen. Even though some networks are clearly

lightening their regulations, advertising for condoms still remains more restricted than advertising for many other products, including other forms of contraception such as the birth control pill.

SOCIAL MARKETING

Although contraceptive ads are sometimes avoided by social marketers, research indicates that television messages promoting condom and other contraceptive use can be highly effective in capturing the attention of the teen population. The social marketing campaign Project ACTION, which was conducted during the early 1990s, is believed to have increased teen condom use with casual partners from 72% to 90% and to have reduced the number of teenagers reporting sexual activity from 82% to 75% in Portland, Oregon. The campaign, which used PSAs, condom vending machines, and teen talk shows about AIDS, was launched by Population Services International (PSI) in 1992 to promote teenage condom use. As part of the campaign, an advertising agency developed TV spots that featured teens fantasizing about sexual encounters being "showered" with condoms falling from the sky. The final words directed viewers to condom vending machines: "Don't even THINK about sex . . . without a condom. Find this condom machine." Local TV and radio stations aired these safe-sex messages totaling 2,800 minutes of PSA time, 78 minutes of news coverage, and 90 minutes of radio. More than 85,000 condoms were sold through vending machines from 1992 to 1994, demonstrating the campaign's effectiveness. It will remain important to document how the acceptance of contraceptive advertising continues to progress in the future.

CONTRACEPTIVE INFORMATION, ONLINE

Although the amount of time and attention that young people spend on the Internet provides an ideal opportunity for communicating about sexual health, few efforts have used the Web for this purpose. The Internet's ability to relay information on demand is ideal for teenagers, who often lack transportation and access to health-care providers. The anonymity of accessing information online may enable more teenagers to seek answers to their questions, questions they would never dare to ask in person. And, although the Internet may contain ample misinformation, studies have shown that careful search techniques can successfully pull up educational information without pornography. Finally, the Internet may be the only source of comprehensive, accurate sexual health information at a time when school-based curricula, at best, are becoming increasingly incomplete.

Of the nation's estimated 144 million regular Internet users, about 31% regularly use the Net for health information, and many of them are teenagers. In 2003, roughly 27 million of the nation's regular Internet surfers were between the ages of 2 and 17. Many teens use this new medium for sexual information. Although teens say they prefer to get sexual education from their parents, 44% report learning about sexual issues from the Internet. Yet, public health educators have done little to examine the viability of the Internet for this role.

Simultaneously, U.S. adolescents face increasing risks of sexually transmitted diseases (STDs) and continued high rates of unintended pregnancies. About one in four sexually active youth are infected with an STD by age 24. About 800,000 teenagers age 19 or younger become pregnant each year, a figure that, although representing a decline from the early 1990s, is still higher than the rate for most developed countries.

The coincidence of these two trends—increasing use of the Internet for health information and an adolescent STD epidemic—provides health educators with a unique opportunity to convey sexual health information and disseminate contraceptives. Online sex stores make it easy for adolescents to buy contraceptive products such as condoms from the comfort of their own computers. This mode of perusal and acquisition offers the advantages of anonymity, accessibility, and affordability, while at the same time exposing users to the disadvantages of inappropriate and inaccurate information.

The Internet's uniquely intermediate status between a mass medium and interpersonal communication makes it an ideal venue for communicating sensitive information because it offers anonymity and sophisticated message tailoring. Several exemplary sexuality education sites are specifically designed for teenagers: Planned Parenthood Federation of America's www.teenwire.org, Sex, Etc.'s www.sexetc.org, and Kaiser's www.kff.org.

The Internet may be especially useful in circumstances where alternative sources of sexual information are limited. Recent federal legislation mandates that schools teach abstinence until marriage unless a broader curriculum is approved by parents and local school boards. The abstinence-until-marriage platform excludes sexually active straight teens and all gay and lesbian people because gay marriage is illegal in 49 states. Yet, in 2005, the U.S. Dept. of Health and Human Services dedicated nearly $170 million in funding to abstinence-only programs, more than twice the amount allocated in 2001, while comprehensive, medically accurate sex education will receive no dedicated funding, according to a 2004 report issued by Rep. Henry A. Waxman (D-CA). The report also stated that the majority of curricula (11 out of 13) funded by the federal abstinence initiative, SPRANS (Special Programs of Regional and National Significance Community-Based Abstinence Education), contain scientific errors and distortions, along with misleading information about the effectiveness of contraceptives, the risks of abortion, and the risks of sexual activity. Taboos on discussing sexuality and other important health topics leave many adolescents unarmed with preventive skills.

The unregulated nature of the Internet also provides a unique opportunity to address subjects that are elsewhere deemed taboo, although this open status may soon give way to screening devices and other regulations. Although the bulk of the Communication Decency Act of 1996 was declared unconstitutional by the Supreme Court on the grounds that it violated the First Amendment, federal attempts are ongoing to regulate children's access to sexual content online.

The Internet has the additional advantage of being able to relay information on demand, meeting young people's needs when they occur, especially important for giving youth access and information about emergency contraception pills (ECP). Before nonprescription ECP was available, Planned Parenthood affiliates provided online medical assessments for ECP in several states, breaking down the barrier for women who lacked access to providers' offices. Today, websites are used as educational tools about ECP side effects and post-marketing feedback. Young people are often not connected to health-care services and may lack transportation or resources to contact providers.

The Internet can facilitate personal decision making, risk assessment, and online peer support through message boards, chat rooms, and email. Online support groups have been shown to positively impact people with AIDS, and the Internet has been shown to promote self-efficacy and model communication skills, prerequisites to safe sex practice and STD prevention.

Clearly, a few limitations remain. For one, inaccurate or inappropriate information is rampant. One study found an abundance of pornography when searching for sexual health websites. Others have found serious misinformation regarding family planning methods. The Food and Drug Administration (FDA) has shut down numerous sites selling illegal birth-control products, including home abortion kits, female self-sterilization kits, and fake birth-control patches. Other researchers have found contradictory information on United Nations and World Health Organization websites about the risk of venous thromboembolism from third-generation oral contraceptives. A 2003 study discovered that many websites misrepresent the IUD's contribution to risks of pelvic inflammatory disease, ectopic pregnancy, and infertility.

Perhaps the greatest impediment to using the Internet as a vehicle for reducing adolescent sexual health risks has to do with access. Although two thirds of urban and suburban Americans are online, only about half of their rural counterparts are connected. Furthermore, poorer users spend less time online; households earning below $25,000 account for just 13% of total online traffic.

Unfortunately, little is known about the effects of online sexual health education and how teenagers use

the Internet to prevent STDs and unwanted pregnancy. At least two articles have reviewed online HIV/AIDS resources, and two examined STD prevention websites. None, however, looked at the effects of specific sites.

We do have reason to believe the Internet can be an effective health communicator. Some patients prefer online counseling to face-to-face interaction, and people may be more likely to be truthful to a computer than to a clinician in reporting HIV risk factors. Adolescents have also been shown more likely to report risky behavior (including sexual acts, drug use and violence) when using audio computer-assisted self-interviewing (audio-CASI) technology, compared to more traditional self-administered questionnaires.

CONTRACEPTIVE INFORMATION, TELEVISION AND

Despite the proliferation of explicit sexual themes in entertainment programming and commercials on television, ads for birth-control devices are still considered taboo among both media companies and many viewers in the United States. It was not until the late 1980s that some networks reversed their policy against airing any contraceptive commercials in paid programming. Although the causal relationship is not clear, research suggests a correlation between adolescent sexual activity and consumption of sexual content on television. This finding, together with the high rates of teen pregnancy in the United States, suggests that mass media could play a role in contraceptive education. However, unlike a number of other countries, the United States has made limited use of mass media for public health messages. Although there are some instances of such efforts, these examples are few and far between, and their effects on teenage behavior have not been clearly evaluated.

With most citing the threat of AIDS, a number of TV stations and print media outlets began accepting condom advertising in 1987. First, San Francisco's KRON-TV, an NBC affiliate, announced it would end its ban and aired three 15-second spots for Trojan condoms in February of that year. Following KRON's lead, all three network affiliates in Detroit—ABC, NBC and CBS—aired advertisements for condoms, as have a number of major print media, including the *New York Times*, Time, Inc. publications, *Newsweek*, and *U.S. News & World Report*. The reaction in San Francisco was very positive; only 2 out of 100 viewers complained. At about the same time, local TV network affiliates around the country also began showing ads for the disposable contraceptive sponge, leading to a doubling in the number of product inquiries received by the manufacturer.

The networks also have a history of rejecting family planning public service announcements, claiming they are too controversial. In 1985, the networks refused to air a PSA entitled "The Facts," which told

young people, “It’s okay to say ‘no,’” but that if they do have sex, then the pill and condom are the safest birth-control methods. Network officials claimed that many of their viewers did not agree with birth control, that they did not want to offend viewers who were opposed to such ads on religious grounds, and that they feared offending existing advertisers. Others said contraception should be discussed only in public affairs and news programs, because news hosts could allow both sides to present their points of view.

Public health experts, meanwhile, questioned the networks’ wisdom, pointing out that the United States leads industrialized countries, with nearly 1 million pregnancies each year for girls ages 15 to 19. The networks’ position was questionable, critics argueed, because daytime soaps and prime-time series such as *Dynasty* routinely glamorized sex without suggesting its risks.

Indeed, over the past two decades, the sexual content on television has increased in frequency and explicitness but has seldom included depiction of the use of contraceptives. Concurrently, the age of initiation of heterosexual intercourse has decreased, and the number of teenaged pregnancies has remained high. A recent survey of 1,000 12-to-14-year-old adolescents found that those who watched a larger number of sexy television shows were more likely to have engaged in sexual behavior than those who viewed a smaller proportion of sexual content on television. This relationship held across race and gender groups and regardless of perceived peer encouragement to engage in sex. Although causal direction is not clear from these data, the relationship suggests either that sexual activity results in increased interest in sexual content in the media or that viewing such content leads to sexual activity—or both. In either case, the finding points to the need for further research and increased discussion and portrayal of the use of contraceptives on television.

Compared to a number of other countries around the world, the United States has not relied extensively on mass media to educate the public about sexual health. Great Britain launched a $30 million, government-funded campaign in 1987 featuring TV ads with the word *AIDS* chiseled on a gravestone; similar ads were run in Denmark, Norway, and West Germany. The U.S. Agency for International Development (USAID) has funded numerous family planning and condom promotion media campaigns throughout the third world, where researchers have found that women who view family planning messages on television, radio, and print media are more likely to use contraceptives than are those who see fewer messages. In Nigeria, in 1993, women who had seen pro–family planning music videos featuring the popular music artist King Sunny Adé were significantly more likely (11%) to be using modern contraceptives than those who did not watch the programming.

Relatively few such campaigns have been conducted in the United States. One exception is the Campaign for Our Children, designed to reduce teen pregnancy in Baltimore, Maryland, in the mid-1980s. The campaign, which included dramatic billboards and television and radio spots, has been credited with contributing to a significant decrease in teen pregnancies. Project ACTION, a U.S. social marketing campaign modeled after a project in Zaire, is believed to have increased teen condom use with casual partners from 72% to 90% and to have reduced the number of teenagers reporting sexual activity from 82% to 75% in Portland, Oregon. The campaign, which used public service announcements (PSAs), condom vending machines, and teen talk shows about AIDS, was launched by Population Services International (PSI) in 1992. More than 85,000 condoms were sold through vending machines from 1992 to 1994.

Perhaps more promising in American media culture are incidents of messages embedded in existing TV dramas. A number of nonprofit agencies have been working closely with Hollywood producers and directors to integrate sexual health plots into scripts of popular TV dramas. A groundbreaker was a 1987 episode of *Kate & Allie* in which Allie has a heart-to-heart with her daughter about having sex with a boyfriend. An episode of *Cagney & Lacey* showed Mary Beth discussing condoms with her son. The long-running hit show *Beverly Hills 90210,* with editorial consultation from the Advocates for Youth Media Project, featured high school characters who either waited to have sex or used contraceptives. The Kaiser Family Foundation has worked with top TV shows such as *ER* to include health information and has partnered directly with popular teen-oriented networks, including MTV, Black Entertainment Television, and UPN on public education campaigns that have included both public service advertising and health content integrated into popular sitcoms and dramas.

COVIEWING

Coviewing, the shared experience of media use among two or more individuals, represents one way in which parents and other significant adults exert an influence over the uses and effects of media by and on children and adolescents. In media effects research, *coviewing* usually refers to parents and children watching television together. More recently, some scholars have broadened their definition to include co-use of the Internet and gaming technologies. Coviewing provides children with an opportunity to observe their parents as models of appropriate media use behavior but represents a relatively passive intervention strategy. Other routes to parental influence include general communication norms, explicit rule making, and active discussion of media, usually referred to as *mediation, active mediation, instructive mediation,* or *evaluative guidance*.

Analysts need to distinguish between coviewing and active mediation because coviewing can occur with or without discussion. Despite the popular view that coviewing should benefit children, coviewing's value is questionable if done without significant evaluative discussion. Often, parents and children watch television together without discussing media content or without discussing it critically, doing so primarily because they like the content and want to share time together. As a result, children appear to interpret coviewing as endorsement. Accordingly, scholars have found that coviewing can increase perceived realism, the learning of aggression, and positive attitudes toward violence and sex.

Parents tend to coview less with older children than with younger children. More frequent coviewers tend to use media more heavily, to speak more positively about television content, to consider television a useful tool, and to possess a more control-oriented communication style. Coviewing appears to be uncorrelated with critical discussion and tends to be positive more often than negative. Nevertheless, while insufficient on its own, coviewing can provide the impetus for discussing issues difficult to bring up in another context, and it can cultivate positive family relationships.

From a theoretical point of view, it appears to matter little which medium is under scrutiny. Although less research exists on parental co-use of new technologies, Peter Nikken and Jeroen Jansz have demonstrated that, as with television coviewing, parents and children tend to play video games together when parents believe that the games have socioemotional benefits. Further paralleling the findings of the television-based studies, Nikken and Jansz have found that what they call *conscious coplaying* occurs more often among parents who play more often themselves and who have younger children.

To measure coviewing, scholars most commonly isolate coviewing behavior from motivations and discussion, often using global measures and more recently measuring it across genres for added reliability and precision. Patti Valkenburg and colleagues have employed a construct called *social coviewing*, which

incorporates motivational characteristics, behavioral patterns, and affirmative discussion. Scholars have suggested that future research should examine the implications of children's perceptions versus parents' perceptions, which often differ, continue to investigate the implications of passive and active communication patterns between significant adults and children, and expand studies to explore the ramifications of peer-to-peer coviewing and coplaying.

CUING AND PRIMING

Directors can use many techniques to signal that a specific element of a media story is important. For example, placing a spotlight on an object or having a camera zoom in on the object makes the object more salient so that people are more likely to notice it. *Cuing* the object signals the audience to pay particular attention to this object in the future. Media psychologists would argue that the cue operates to *prime* a particular object or person. *Priming* refers to the effect of some preceding stimulus or event on how we react to some subsequent event or person. The effect is analogous to what happens when a water well is primed. Priming the well enables it to produce water when it is pumped at a later time. As applied to the media, *priming* refers to the effects of the content of the media (e.g., extensive coverage of certain political stories, depictions of violence, the use of brief "teasers" about an upcoming story on a newscast) on people's later behavior or judgments (e.g., evaluations of the president, aggressive behavior, attention to news stories related to the teaser).

There are three important characteristics of priming. First, the effect of a prime dissipates with time. Typically, the effects of a prime on social judgments fade within 20 to 30 minutes (but may last up to an hour). Second, primes that are more intense will tend to have stronger effects on people's judgments and behavior. Third, primes tend to have stronger effects when a situation is more ambiguous. For example, if I have just watched a violent TV show, I am more likely to interpret someone's accidentally bumping into me as intentional and to react with hostility than if I had just watched a nonviolent show such as *Sesame Street.*

Cognitive and social psychologists have used priming paradigms since the early 1970s to study various aspects of the cognitive system. Given the extensive research on priming within social and cognitive psychology, it is not surprising that priming has been found useful as an explanation of a number of the effects of the media on people's thoughts, beliefs,

judgments, and behavior. For several reasons, the characteristics of the media make it a likely source of priming. First, the ubiquitous nature of the media in our lives makes it a powerful tool for priming various concepts—often outside our awareness—that may influence how we interpret later information. In particular, situations in which we have the TV on but are not paying particular attention to it are ideal for priming because explicit awareness of a prime often mitigates the influence of the prime. Second, particular types of media, most notably the news, are well suited to act as primes. A typical newscast will cover a wide variety of topics that may result in the priming of a correspondingly wide variety of concepts. Such priming increases the likelihood that one of the primed items will influence how we interpret later ambiguous information. In addition, any particular story (e.g., the war in Iraq or President Clinton's sexual liaisons) will receive extensive coverage across time, which may result in related concepts (foreign policy or sexual indiscretion) being primed for an extended period of time.

The most prominent area of research dealing with priming among children and adolescents is media violence. In general, the results of the research are consistent with the priming explanation of media violence. When people are exposed to violent behavior on TV or in movies, they are more likely to think about violence, interpret ambiguous behavior in a hostile manner, and act more aggressively. For example, Wendy L. Josephson found that, if boys were primed with aggressive media and then played field hockey, they acted more aggressively (hit other boys with the hockey sticks or pushed other boys over) than did boys who were not exposed to a violent program. Further, consistent with the time-course of priming, the boys were most likely to act aggressively within the first 3 minutes of play. Another interesting aspect of Josephson's study was that the men who were violent in the media clip used walkie-talkies to communicate with each other. Prior to playing field hockey, some of the boys in the study were interviewed using walkie-talkies similar to those used in the media clip. Of interest was whether the walkie-talkies would act as a cue to remind the boys of the clip they had just watched. Consistent with a cuing hypothesis, the boys who were cued with the walkie-talkies acted more aggressively than did boys who were interviewed with a standard microphone.

There is also an extensive literature on the impact of political news as a form of media priming. Priming also has been used to explain the effects of rock music videos on gender stereotyping, the interpretation of ambiguous print advertisements, the impact of news teasers on attention to and memory for news stories, stereotyped judgments of blacks and women, and perceptions of rape.

Research has also demonstrated that stereotyped media portrayals of minorities will prime how individuals make judgments about minorities they encounter in day-to-day settings. Unfortunately, there has been no research focusing on the priming of racial stereotypes in young children or adolescents.

CULTIVATION THEORY

Cultivation theory, developed by George Gerbner and his colleagues, proposes that heavy television viewing contributes to beliefs about the real world. The more

television people watch, the more their beliefs and assumptions about life and society will tend to be congruent with television's most stable and repetitive messages.

The theory of cultivation emphasizes the role that storytelling plays in the process of socialization. Stories—from myths and legends to soap operas and cop shows—tend to express, define, and sustain (i.e., cultivate) a culture's central assumptions, expectations, values, and interpretations of social reality. Much of what we know, or think we know, comes not from personal or direct experience but from many forms and modes of storytelling. In earlier times, cultural stories were told face to face by members of a community, parents, teachers, or the clergy. Today, television is the dominant storyteller. Television's stories must fit into and reflect—and thereby sustain and cultivate—the "facts" of life that most people take for granted.

Cultivation is part of the *cultural indicators paradigm*, which follows a three-pronged research strategy. The first step, *institutional process analysis*, investigates the pressures and constraints under which media messages are selected, produced, and distributed. The second, *message system analysis*, systematically monitors the most stable images and recurrent portrayals in television content. The third, *cultivation analysis,* explores whether and how television viewing contributes to audience members' conceptions of social reality.

Findings from message system analyses of television's content are used to formulate questions about social reality, often contrasting television's "reality" with some other, real-world criterion. Using standard techniques of survey methodology, the questions are posed to samples of children, adolescents, or adults, and the differences (if any) in the beliefs of light, medium, and heavy viewers, other things held constant, are assessed.

LONG-TERM SYSTEMIC EFFECTS

Before cultivation theory was developed in the late 1960s, most studies of media effects looked at whether individual messages or programs could produce some kind of change in audience attitudes or behaviors, typically in an experimental context. These studies looked for immediate effects following exposure to a single message or stimulus. In contrast, cultivation theory sees television as a coherent *system* of messages—a symbolic environment—and asks whether that system as a whole might promote long-term changes rather than immediate change in individuals. Cultivation thus focuses on the cumulative consequences of television exposure, not on short-term responses to or individual interpretations of content.

Early cultivation research was concerned with the issue of violence. Whereas most research on television violence explored whether violent portrayals make viewers more aggressive, Gerbner and his colleagues tested the hypothesis that heavy exposure to television cultivates exaggerated beliefs about the amount of violence in society. Over the years, the investigation expanded to include sex roles, images of aging, political orientations, environmental attitudes, images of science, health, religion, minorities, occupations, and many other topics.

The consistent overrepresentation of well-off white males pervades prime time. Women are outnumbered by men at a rate of three to one and have a narrower range of activities and opportunities. Members of the dominant white male group are more likely to commit violence, whereas old, young, female, and minority characters are more likely to be victims. Crime in prime time is at least 10 times as rampant as in the real world, and an average of five to six acts of overt physical violence per hour involve well over half of all major characters.

Those who watch more television overestimate their chances of being involved in violence and express a heightened sense of danger. This is the *mean world syndrome* of insecurity, apprehension, and mistrust. Above and beyond the effects of background factors, heavy viewers express a greater sense of apprehension and victimization than do light viewers in the same groups, and their images of crime more closely match television portrayals. Children and adolescents are especially susceptible to television's messages about traditional gender roles. Cultivation researchers argue that these messages help maintain the prevailing hierarchy of social power.

Cultivation is not a linear, unidirectional, mechanical "effect" in the sense of a stimulus-response model but part of a continual, dynamic, ongoing process of interaction among messages and contexts. Television viewing usually relates in different ways to different groups' life situations and worldviews. For example, personal interaction with family and peers makes a difference, as do real-world experiences. A wide variety of sociodemographic and individual factors produce sharp variations in cultivation

patterns. The most common of these is a phenomenon called *mainstreaming*, whereby heavy television viewing tends to erode differences in people's perspectives that stem from other factors and influences.

Cultivation has been a highly controversial and provocative approach. Cultivation analysis has been critiqued on theoretical, methodological, and epistemological grounds. Hundreds of cultivation studies have been published in the past three decades, and replications with children and adolescents have been carried out in over a dozen other countries, including Argentina, Australia, China, the Netherlands, South Korea, Sweden, Taiwan, and others. The literature contains numerous failures to support cultivation theory as well as numerous independent confirmations and replications. The most common conclusion, supported by meta-analysis, is that television makes a small but significant contribution to heavy viewers' beliefs about the world.

CONCLUSION

Cultivation theory provides a unique way to think about the enduring and common consequences of growing up and living with television. As media channels and new delivery systems proliferate, and as audiences continue to fragment, cultivation theory will continue to focus on the most general implications of long-term exposure to centrally produced, commercially supported systems of stories. This will be of vital importance as institutional, technological, and policy-related changes continue to unfold.

CULTURAL IDENTITY

Culture is generally defined as shared and learned behavior and meanings that are socially transferred. Culture incorporates the shared values, traditions, norms, customs, arts, history, folklore, and institutions of a people. It embodies our worldviews, perceptions, and orientations, and it shapes our language, our education, our gender roles, and our expectations of youth. Cultural groups share values and traditions. Clifford Geertz suggests that individuals who belong to the same culture go about their daily lives within shared webs of meaning. These shared webs are unconscious and consist of both seen and unseen cultural norms. Among youth, these cultural norms are expressed in the clothes they wear, the music they listen to, the friends they hang out with, their language, and even whether they go to college. But the question of whether cultural identity positions the media or whether the media position cultural identity has yet to be answered.

ETHNIC VERSUS CULTURAL IDENTITY

Although culture often corresponds to nationality or ethnicity, ethnic identity is not the same as cultural identity. Although ethnic identity may be the organizing feature of different nationalities or ethnic groups, Jean S. Phinney's literature review of ethnic identity suggests that understanding how ethnicity distinguishes differing ethnic groups is complex. Whereas youth living within the same nation may have different cultures, youth of different ethnicities may actually share similar cultural values. Many youth of the same ethnicity live vastly different lives shaped by cultural bonds and identification. Youth within a specific racial, ethnic, language, nationality, or religious group are not homogeneous even though they may hold cultural beliefs, practices, and institutions in common. People's primary cultural identification is with the group toward which they most strongly feel a sense of belonging.

CULTURAL IDENTITY IN YOUTH

Shared values are powerful transmitters of culture. Culture determines how youth life is shaped, and cultural identity is the degree to which youth identify with the cultural norms of a specific group. Children identify with groups very early in their development.

They first identify with family, later with friends, then later still with larger groups that use music, clothes, and social behavior to distinguish themselves as a group. Adolescents who grow up experiencing diverse cultures increasingly develop multicultural identities.

Cultural identity is not necessarily a logical and systematically defined term, but it is broader than *ethnic identity*. *Ethnic identity* typically refers to one's membership in a social group that has a common culture marked by shared language, history, geography, and sometimes physical characteristics. Cultural identity with a specific group can include people from many different ethnic backgrounds. Therefore, many different ethnic groups of youth can identify with the same culture, as for example, those youth who belong to the hip-hop generation or Generation X. Cultural identity has not been extensively studied in children and adolescents and, until recently, has rarely appeared in the scientific literature. A few studies have examined cultural identity and its relationship to mental health in youth and show that strong cultural identity is associated with lower levels of adolescent mental health problems. Overall, however, the relationship between cultural identity and general functioning in adolescence is not well understood.

THE ROLE OF THE MEDIA

Youth are immersed in the media images of their culture from television to radio to films, and youth culture is depicted in these images. The media are a powerful influence in the development of cultural identity in youth. Through advertising, television, music, print, and the Internet, youth are constantly bombarded with images, ideas, products, and lifestyle choices. Much of the media's influence on youth cultural identity is visible in the way they dress, talk, act, and behave.

Frequently, the essence of a culture is expressed through its proverbs and traditional sayings. For example, the African saying "It takes a village to raise a child" expresses community support for persons outside the nuclear family becoming directly involved with disciplining and directing a child. In the youth culture, the media plays a powerful role in influencing the language of youth culture. Slogans from advertising campaigns are seen on clothes from the youngest to the oldest child, and these slogans become integrated into the everyday language of youth. They become powerful predictors of youth behavior. The media's influence on youth language can also be seen in everyday speech. Words and phrases coined by popular characters on television shows (e.g., the character from the television show *Saturday Night Live* used the term *shwing*) become part of the language of everyday youth culture. Youth identify with these characters and their language, and thus the language symbolizes the attitudes portrayed by the television characters.

Music is another powerful influence on cultural identity. Youth frequently maintain a cultural identity that is ruled by musical genre. It is rare to find youth who cross over from one genre to another. Youth who listen to country music identify with the culture of the country music portrayed in lyrics and lifestyle. Similarly, hip hop, rock, and heavy metal have their own specific cultural nuances with which youth identify.

Visual media influence youth cultural identity through art, print, television, and movies. Young artists identify with an entire youth culture that is based on the work of cartoonists, comic-book artists and writers, and graffiti artists. The artistic medium influences much of youth behavior through its stories and activities. Comic-book heroes have spawned a whole culture of youth dedicated to wearing and acting out the story lines of their specific heroes. Graffiti, a lesser-known but highly visible art form, is a medium created by and for youth for the specific purposes of expressing youth values. The identification of any of these cultures predicts a certain style of dress, a set of behaviors, and most probably the pursuit of a specific lifestyle.

Advertisements are responsible for creating or helping particular youth cultures flourish. Very little research has been conducted to determine which comes first, the media image or the cultural norm. Cultural values and attitudes are manifestations of cultural identity, and these values and attitudes affect how the specific form of media is interpreted and used. The youth culture has specific beliefs about health, life, love, traditions, and customs, and advertising uses these cultural norms to be effective.

Is cultural identity in youth shaped by these media images, or do they shape the images according to their cultural norms? Andrea Zlatar suggests that media are the most powerful conveyors of messages to adolescents because they become instruments of cultural policy—shaping, governing, and strengthening cultural identity through an omnipresent system of communication.

D

DAYTIME TALK SHOWS

The daytime television talk show reached the apex of its popularity in the mid-1990s, with more than two dozen options available daily. Public criticism of such shows reached its peak at that time, too, focusing on the often bizarre participants, the emphasis on sexual deviance, and the frequent use of "ambush" techniques to startle guests and audience. In 2005, a dozen staples remained, ranging from the much-decorated *Oprah Winfrey Show* (about 10 million viewers) to the much-maligned *Jerry Springer Show* (about 3 million).

The quantitative literature on television talk shows is limited to a few studies of content and its effects, and these largely date to the genre's period of peak popularity. One primary project, funded by the Kaiser Family Foundation, generated a 1995 video sample of 10 episodes from 12 top-rated shows and a nonredundant sample of 10 transcripts from 8 of these shows, as well as a study of nearly 1,000 talk show titles.

Analysis of the video sample by Bradley S. Greenberg and colleagues (1997) identified the guests as 2 to 1 female; 46% were in their 20s, and 75% were Caucasian. The major groups of discussion topics on the shows were family issues (parenting, marriage, dating), sex issues (activity, infidelity, orientation) and crime (criminal acts, abuse, addiction). The specific topics represented on at least 10% of the talk show sample were parent-child themes (48%), dating (36%), marital relations (35%), sexual activity (34%), reconciliation (25%), physical health (24%), abuse (23%), alienation (23%), appearance (23%), criminal acts (22%), sexual infidelity (18%), addiction (12%), mental health (11%), and sexual orientation (11%). The major variant in topic choice was gender: Male guests were more likely to deal with sexual orientation, whereas females more often discussed psychological topics, such as addiction, alienation, and mental health.

The transcript analysis profiled personal disclosure and privacy issues on daytime talk shows. Self-disclosure accounted for 42%, with disclosure by the host (28%) and others with a personal relationship to the guest (30%) accounting for more than half. Overall, the average number of disclosures per talk show hour was 15, with a predominance of sexual activity disclosures (3.5 per hour), primarily frequency, pregnancy, and infidelity; abuse (2.7 per hour); criminal activity (2 per hour); and an array of personal attributes (4 per hour), primarily addiction and mental and physical health issues. Televised self-disclosures received negative reactions from the host and the relational partner in 30% of those instances. However, for ambush disclosures, the ambushed guest responded with some form of face-saving strategy 85% of the time.

The amount of "expert opinion" in talk shows was assessed by *talk turns*, or the number of times a particular person initiates a conversation. Experts accounted for 3% of all speaking turns, as compared with nonexpert guests (53%) and the host (39%).

In a 1999 study of 955 talk show titles, Sandi Smith and colleagues reported that 30% of all titles reflected family relationships, 27% personal relationships, and 74% individual attributes of the guests. Among guest attributes, sexual activity accounted for 20%, personality traits for 19%, and criminal activity for 10%. All

these were further coded as to whether the title reflected positive, neutral, or negative attributes; negative emphases were consistently identified. Sexual activity disclosures occurred more so with personal relationships than with family relationships. Sexual orientation disclosures and embarrassing situation disclosures occurred more with positive personal relationships. Abuse disclosures were most likely to be found with negative personal relationships. No more recent systematic analysis of talk show content has been identified.

Patricia J. Priest, in her notable 1995 interview of 40 talk show participants, reported that they had four major motivations: to remedy stereotypes, to seek 15 minutes of fame, to plead their cases against those who had victimized them, or to market a business venture. She characterized these guests primarily as outliers who were members of marginalized groups at the fringe of society.

The concern with talk show content has not manifested itself in much research that attempts to determine its social and behavioral effects. One study indicates that the audience that favors this personal disclosure format itself has relatively high self-disclosure scores. The primary motives of undergraduates in watching these talk shows have been identified as to be entertained ("It amuses me"), to pass the time ("Nothing better to do"), and to relax. The females in the study watched the shows 3.2 hours per week; the males, 2 hours per week.

Cynthia M. Frisby compared the responses of high- and low-self-esteem subjects to taped instances of upward and downward social comparisons among 232 talk show viewers. Both esteem levels in response to both social comparisons showed increases in life satisfaction measures, with the high-self-esteem group obtaining even more positive benefits from the downward social comparison exposure.

Stacy Davis and Marie-Louise Mares interviewed 282 high school students and asked them to estimate how many people do the kinds of things commonly seen or discussed on talk shows, for example, premarital sex, infidelity, teenage pregnancy. They also assessed desensitization (how wrong the perpetrator was and how much the victim suffered) and the seriousness and complexity of issues common and rare on TV talk shows. Comparisons were made among subgroups differing in the amount of talk show viewing they did. The primary finding was a significant effect of viewing on the estimates of behaviors discussed on these shows, but only on teen-related topics. In addition, viewing was related to the perceived seriousness of the problem of teenage pregnancy.

Hyung-Jin Woo and Joseph R. Dominick examined international college students who viewed different amounts of TV talk shows, and then compared their perceptions with those of a comparable group of U.S. students. Within their own group, the international students who were the heaviest viewers of TV talk shows overestimated the frequency of undesirable behaviors in the United States and had more negative attitudes toward and more negative perceptions of human relationships in this country. When compared with domestic viewers, the international students demonstrated a consistently stronger correlation between their viewing and each of these same outcome measures.

—Bradley S. Greenberg

DEPRESSION, MEDIA USE AND

Depression is a mental disorder marked by feelings of sadness, loss of interest, and hopelessness. According to the World Health Organization, it is one of the most common mental illnesses, and if it becomes chronic, it can affect an individual's daily functioning. Adolescence is a time of emotional upheaval, during which individuals are particularly vulnerable to depression. The U.S. Department of Health and Human Services estimates that mental health problems affect one in five children and adolescents. They further estimate that 10% to 15% of all children and adolescents have some symptoms of depression. Signs of depression in adolescence include boredom, hopelessness, unexplained crying, reckless behavior, and loss of interest in usual activities. Although it is common, depression is an especially significant problem in adolescence because of its association with teen suicide. The adolescent suicide rate has increased in recent years. Statistics reveal that almost 5,000 U.S. adolescents committed suicide in 1995. Studies estimate that between 5% and 8% of U.S. youth attempt suicide. It is now the third most common cause of death for adolescents, following unintentional injuries and homicide.

The mass media play a role in adolescent depression and suicide. First, mass media content can affect adolescents' beliefs about mental illness. Second, media use can be a symptom of or a treatment for mental illness. Third, media use can be a cause of depression. Fourth, media representations of suicide can have a contagion effect, leading to suicide.

MEDIA CONTENT AND BELIEFS AND MENTAL ILLNESS

Children and adolescents consume a good deal of media. Research suggests that younger adolescents are especially susceptible to its influences, especially in areas in which they have little direct experience. The topic of mental illness is often taboo in private conversation, yet it is a common topic in drama and on talk television. Indeed, research concludes that the mass media are a prime source of information about mental illness. Unfortunately, media depictions of mental illness are often inaccurate and negative. Content analyses of prime-time U.S. television found that the mentally ill are characterized as "bad," violent, and negatively affecting society. These negative media images can lead depressed adolescents to be reluctant to seek treatment and can contribute further to their feelings of worthlessness.

MEDIA USE AS SYMPTOM OR TREATMENT OF DEPRESSION

Although there is little evidence that media use causes depression, excessive media use is more likely a symptom of depression. Depression is often associated with changes in sleep routines. Heavy television viewing, especially late at night, can be a way for a depressed young person to fill lonely hours. Research has shown that adolescents with fewer social skills are more likely to use the Internet excessively and to access problematic content. Listening to heavy metal music, with its themes of violence and hopelessness, has been found to be a mark of troubled youth. Heavy metal listeners are more likely to report feelings of depression and thoughts of suicide. Some have speculated that troubled youth are drawn to media content that supports their depressed view of reality.

On the other hand, there is some evidence that people can use the media to try to reduce dysphoric feelings. The theory of affect-dependent stimulus arrangement described by Zillmann and Bryant (1985) asserts that people are motivated to manipulate their environments to maximize pleasure and reduce aversive feelings. There is evidence that depression leads older adolescents to television viewing as a way to cope with negative moods. Depressed college undergraduates watch more television than their nondepressed peers. And, although researchers did not find a clear connection between depression and television viewing, they did find that depressed college undergraduates

watched television to overcome loneliness and to get away from people. Still another study found that older adolescents who were in bad moods listened to more lively, joyful music than their peers in better moods. In all, these studies support the hypothesis that media use can be a way to cope with negative moods.

MEDIA USE AS A CAUSE OF DEPRESSION

Concerns that depressing media content is the cause of negative moods has been an enduring concern of media researchers since the days of radio serial research. Although some writers assert that excessive media use—including heavy television viewing, Internet use, and heavy metal music—leads to depression in youth, there is little evidence that media use itself causes depression. Research about the causes of depression has focused on the impact of news and media violence. Scholars and public health officials were concerned that news coverage of the 1986 explosion of the space shuttle Challenger would lead to depression among children, especially as children had been encouraged to watch the launch and study about space because Christa McAuliffe, a teacher, was one of the astronauts. Others were concerned that coverage of the cold war arms race would lead adolescents to feel hopeless about the future.

Most research, however, has focused on the impact of media violence on feelings of depression. Scholars have found that exposure to violent media content leads children and adolescents to become fearful of the real world and cultivates distrust of others. Other research has found that, just as exposure to real violence can lead to traumatic stress and depression, so can exposure to media violence.

CONTAGION EFFECTS

Worries about contagion effects of publicized suicides have existed since the 18th century. Goethe's novel *The Sorrows of Young Werther,* which portrayed the suicide of its lovelorn hero, reportedly led to copycat suicides and subsequent banning of the novel. The suicide contagion effect is called the *Werther effect*, after that hero. Cluster suicides do occur, and scholars estimate that they are two to four times more likely among 15-to-19-year-olds. Mental health practitioners believe that adolescents are particularly vulnerable to contagion effects because they romanticize death and believe that suicide is a way to punish someone, to express love, or to be reunited with someone who has died. In general, suicidal adolescents do not understand the permanence of their actions.

There are concerns that fictional media content can stimulate contagion effects. Suicide, including attempts and gestures, are a regular fictional theme. Scholars often comment that, in most cases, the stories do not include discussions of suicide's permanence or its emotional effects on the survivors. In fact, research conducted outside the United States has found contagion effects of fictional suicides.

Most concern focuses on the coverage of suicide in the news. Media coverage of the suicides of entertainers or politicians is typically associated with an increase in suicides. In fact, there is evidence that, as coverage increases, so does the number of copycat suicides. Consistent with professionals' beliefs that adolescents are more vulnerable to contagion effects, there are reports that these effects are strongest for teens.

Recognizing the impact that the media can have on adolescent suicide, media scholars have developed recommendations for reporting on suicide (Gould, Jamieson, & Romer, 2003). These recommendations include (a) report on underlying and longer-term contributions to suicide, such as mental illness and substance abuse; (b) avoid reporting the overly emotional reactions of family members so that adolescents do not view suicide as a way to gain attention; (c) use restraint in including the word *suicide* in headlines; (d) cover celebrity suicides especially carefully; reports should take care to prevent celebrity and glamour from overshadowing reports on the underlying causes of the suicide.

DESENSITIZATION EFFECTS

Desensitization is a process through which repeated exposure, without incident, to a stimulus that naturally evokes a powerful emotional response leads to a lessening of that response. That is, if a subject is repeatedly exposed to a stimulus, and if no negative outcome arises from the exposure, the subject's reaction to the exposure will eventually be lessened. The desensitization principle can be applied in a variety of ways, from helping arachnophobes overcome their fear of spiders to training soldiers to circumvent their natural aversion to killing.

An unintended and allegedly undesirable example of desensitization occurs when repeated exposure to violent media content causes audiences, especially children, to become desensitized or "numbed" to the notion of violence. Many people, including what appears to be the majority of social science researchers, assert that the desensitization effect is undesirable in this context because it can be associated with an increased likelihood that viewers of media violence will be more tolerant or accepting of real-life violence. There is also the belief that desensitized subjects may exhibit more violent attitudes or even more violent behavior than before the desensitization, although there is less agreement on this purported effect.

Researchers generally agree that the desensitization effect is real. There is also widespread consensus that children are more susceptible to the effect than adults. The classic study of desensitization in children, which has been repeated several times, shows that children who are shown violent media wait longer to respond when staged incidents of violence occur in their presence. Children who have not been the subjects of experimental desensitization treatments consistently respond more quickly and more profoundly when they witness violence.

However, being apathetic to violence and committing violence are two different things, and there is less agreement as to whether the desensitization effect causes violent behavior in children or anyone else. Critics fault experimental methods as artificial and invalid as predictors of real-life reactions. They also argue that other factors may explain what seems to be a case of cause and effect. For instance, people who enjoy violence or aggression, or who have higher tendencies to be violent or aggressive, may seek out violent media more than other people do. Therefore, it may not be the media or the desensitization effect that causes violent behavior, but rather the proclivity for violence that causes some to seek out violent media in greater proportion.

Causation is also the most difficult element to establish in pursuing support for various media effects theories. There is strong and widespread support for the notion that desensitization definitely occurs from the consumption of violent media. Somewhat more tenuous is the assertion that this desensitization causes children to be more violent. Some groups, however, including the American Psychiatric Association, do not hesitate to make that claim, asserting that desensitization does indeed lead directly to increases in violent behavior.

DESIGNATED DRIVER ADVERTISING CAMPAIGNS

In the United States, more than 17,000 people died in alcohol-related motor vehicle crashes during 2003; this figure represented 40% of all traffic-related

deaths. One approach to reducing instances of impaired driving is to promote the use of a *designated driver*, defined as an individual who agrees to remain sober, for example during a party, and thus is able to drive others home safely.

William DeJong and Jay Winsten, exploring mass media approaches in communicating about substance use prevention to American youth, cite the Harvard Alcohol Project as a case in point. The project's key objectives include encouraging the use of designated drivers and shifting social norms about the acceptability of driving after drinking alcohol, yet simultaneously conveying that designated driver programs should not be equated with excessive drinking consumption among passengers. Winsten points to national public opinion polls to assert that the project has had a marked impact on awareness, acceptance, and usage of the designated driver concept.

The results of many mass media programs have been limited, however, reflecting that a clearly defined target market is not always apparent, and many ad campaigns utilize donated (rather than paid) media, thus ads commonly have less desirable placements and reduced production quality. John Lastovicka and colleagues have proposed a lifestyle typology to determine appropriate segments for media efforts, with young males who are "Good Timers" (i.e., heavy partiers with a macho and sensation-seeking orientation) identified as a high-priority target. Furthermore, when assessing the effectiveness of various ad campaigns, a study by Lisa Szykman and colleagues suggests that consumers process anti-drinking-and-driving messages differently depending on the ad's sponsor. A designated driver ad from Mothers Against Drunk Driving (MADD) is thought to be more credible than a corresponding message from Budweiser because a nonprofit organization is seen to have positive, society-serving motives, whereas a for-profit sponsor infers more negative, self-serving (ulterior) motives that might lead consumers to question the reasons for sponsorship and discount the content of the message. Kevin Boots and Richard Midford found that an Australian designated driver intervention for young adults known as "Pick-a-Skipper" was effective in reducing drinking and driving.

Health behavior models have specified the conditions under which individuals are likely to engage in desired health behaviors. Protection motivation theory, for example, suggests that people will respond to a health threat in the desired direction only if they perceive a severe threat, see themselves as vulnerable, and perceive themselves and the preventative behavior to be efficacious. These theories place emphasis on cognitive processes mediating behavioral change; however, they often ignore the context in which health decisions are made (e.g., sober versus impaired decision making). Additionally, some messaging may actually work counter to the stated goals of advocacy groups. According to reactance theory, whenever we perceive an unfair threat to our freedom of action, we experience a state of reactance—heightened motivation to perform the threatened behavior. Consequently, if adolescents perceive a given communication as an attempt to restrict their freedom (e.g., "Don't drink and drive—it's the law"), the influence attempt may actually increase motivation to perform the very action that it was designed to prevent.

DEVELOPMENTAL DIFFERENCES, MEDIA AND

Public debate about the potential consequences of children's exposure to mass media has been a frequent theme of social discourse ever since the advent of motion pictures. Does media exposure disrupt children's sleep? Does it foster poor academic performance? Does it inspire aggressive, if not delinquent, behavior? With the introduction of each subsequent new media technology, questions such as these have been common and recurrent. In response, investigators have assembled a tremendous and diverse volume of literature illustrating that the impact of mass media on children is conditional and selective, depending on characteristics of the media message, the child, and the environment. This entry examines some aspects of child and adolescent cognitive and psychological development that are particularly important for understanding the effects of the mass media in the lives of young people.

EARLY RESEARCH ON CHILDREN AND MOTION PICTURES

In the 1920s, motion pictures thrust themselves into the lives of virtually everyone in America. Going to the movies was fun, inexpensive recreation and a frequent event for virtually every family. This national obsession with the new medium, however, sparked considerable concern over what the movies were doing to children.

In an attempt to determine the effect of motion pictures on children of different ages, the Motion Picture Research Council initiated a series of investigations. These studies, conducted between 1929 and 1932 and funded by the Payne Fund, provide fascinating insights into how developmental differences can mediate reactions to media messages. The investigations of three research teams are of particular relevance for our deliberations.

To examine the acquisition and retention of factual information presented in films, Holaday and Stoddard worked with more than 3,000 children and adults and 17 different motion pictures. Their work revealed that even 8-year-old children acquired a substantial number of ideas from films (about 60% of that acquired by adults). Indeed, the retention of information by all age groups was surprisingly high, leading the investigators to conclude that movies provide a "special learning format" yielding an unusually high retention of factual material compared to the acquisition of facts in standard memory tasks.

Dysinger and Ruckmick studied affective reactions to films. Using neurophysiological changes as indices of emotional arousal, they worked with several age categories of children and some adults (for comparison purposes). They found that scenes of danger, conflict, and tragedy produced the greatest effects on children of all ages. Romantic and erotic scenes, on the other hand, didn't seem to do much for very young children, but they were very arousing for 16-year-olds. Adults, by comparison, showed little emotional arousal to any of the scenes. The authors concluded that adults had learned to discount the films as fantasy, but children experienced substantial emotional arousal.

Finally, in a series of two dozen experiments involving thousands of children in grades 6 to 12, Peterson and Thurstone found that the attitudes of children were definitely influenced by some films. These effects tended to be greater for younger children, and seeing two or three pictures treating the same topic in the same way achieved greater results than seeing a single film. Furthermore, their findings showed that attitude changes resulting from exposure to motion pictures persisted for long periods of time.

The discoveries illuminated by these researches, all of which were conducted with *silent* films, provided the foundation of our understanding of developmental differences in media effects. In fact, it is these three areas of inquiry—acquisition of information from media, affective reactions to media, and responses to persuasive media—that remain the primary focus of contemporary research. This entry focuses on developmental differences in acquisition of information from media and in response to persuasive media.

ACQUISITION OF INFORMATION

Building on the classic work of cognitive psychologists such as Piaget and Bandura, Valkenburg identified four cognitive-developmental stages that children

pass through in their development as media consumers. This model, which projects children as active explorers of their media environment, provides a valuable framework for understanding contemporary research on developmental differences in mass media effects.

In stage 1, during the first 2 years of life, infants and toddlers primarily notice bright, colorful, moving images. Although they tend to be cognitively and physically active while using the media, they primarily react to salient and vivid auditory and visual stimuli. There is little evidence that children comprehend media content prior to 24 months of age.

Enjoying their budding cognitive capacities, preschoolers (2 to 5 years old) begin to evidence comprehension and enjoyment of some media content. Initially, their skills are rudimentary, however, as they have not yet assembled a foundation of prior knowledge and experiences. Consequently, preschoolers tend to prefer media content that offers a slow pace and lots of repetition. During this stage, several developmental milestones are evident. Preschoolers begin to actively express preferences for media content, and the ability to distinguish between fantasy and reality slowly emerges. But at the same time, preschoolers tend to comprehend television very literally, constructing their perceptions of TV characters on single, physical attributes without integrating them into an overall picture.

The clear demonstration of greater media competence is evident by the third stage (5 to 8 years old). Children in this stage display a preference for faster-paced, more complex entertainment and often seek themes of action, adventure, and violence projected within storylines that incorporate a community of peers and friends. With the tendency to interpret media content literally on the decline, and the ability to distinguish fantasy and reality in transition, early elementary school children can recognize that costumed characters, unrealistic stunts, and special effects on television are unreal; but they still consider as real things that look real on television.

In the last stage, later elementary school children (9 to 12 years old) make the transition to more adult styles of media comprehension and begin to exhibit critical and abstract thinking when consuming media content. Specifically, they begin to exhibit attributes characteristic of adolescents, including a more social orientation—evidenced by increased sensitivity to the thoughts, opinions, and emotions of others, the ability to understand the difference between fantasy and reality, and a preference for entertainment content designed for adults.

As children mature into adolescence, they continue to extend their cognitive and psychological development and to expand the foundation of prior knowledge and experiences from which they will comprehend and interpret media content. It is important, however, to recognize that, even at this stage, young people remain vulnerable. Contemporary research highlights the fact that the medium through which information is conveyed—whether it is print, audio, visual, or a combination of these—can itself affect how children acquire information and represent it in memory. In general, audiovisual presentations, such as those offered by television and film, continue even today to be a "special learning environment" for adolescents. Perhaps because television and film images can look more "real" than real life, or perhaps because they often demand little investment of mental effort to acquire, adolescents easily can be misled or confused by imagery projected by these media.

This point is illustrated clearly by research examining the effects of distorting forms of humor in educational television programs. Specifically, fourth- and eighth-grade children were shown an educational television program that contained (a) distortion-free humor, (b) exaggeration, (c) irony, and (d) ironic humor followed by a correction of the humorous distortion. Compared with distortion-free humor, irony resulted in the misperception of properties of novel objects introduced in the program. Correction after irony largely failed to remove the perceptual distortion. Exaggeration tended to produce overestimation of object properties. Counter to initial expectations, susceptibility to perceptual distortions from humor did not diminish with age, suggesting that the negative impact on information acquisition occasioned by the involvement of such humor reaches farther up the developmental scale than had been previously thought.

RESPONSES TO PERSUASIVE MEDIA

Many of the most prevalent concerns about children, adolescents, and the media center on potential responses to persuasive messages, especially advertising. It is recognized, for example, that young children (stage 1) cannot discriminate between program and commercial content, do not understand the selling intent of commercials, and have no comprehension of the economics of mass media. However, even at a very

early age, children can identify commercials, perhaps because many of the most salient and vivid images on television are commercials, and they start asking for products.

Preschool children (stage 2), as would be expected, also exhibit little comprehension of the selling intent of advertising—they do not understand that commercials are meant to sell products. Instead, their comprehension and interpretation of advertising is typically very literal. Preschool children, consequently, are very vulnerable to persuasive appeals.

As children grow older (stage 3), they display greater understanding of the selling intentions of advertising. For example, although most early elementary school children express suspicion about the truth (or lack thereof) of commercials, only about a third of 5-to-7-year-olds understand the selling purpose of ads. By age 11, the suspicions about commercials reported by almost all children are based on an understanding of the advertisers' motivation to sell products.

Another concern about children's responses to persuasive media involves the comprehension of advertising disclaimers. Disclaimer statements such as "batteries not included" are intended to qualify or explicate persuasive appeals. However, disclaimers typically incorporate adult nomenclature displayed briefly in very small text or rapidly spoken—presentation styles that are difficult, if not impossible, for most children *and* adults to understand. Especially for younger children, when the imagery conveyed by a commercial and the conditions for product use detailed in a disclaimer are not synchronized (e.g., when performance expectations of a toy are not realized during play), behavioral consequences as well as enduring and lasting emotional consequences may result.

INTERACTIVE MEDIA

A clear pattern of research findings is not yet available that illustrates if or how we should alter our expectations of interactive media, such as video games and computer games, within the four cognitive-developmental stages outlined previously. Some evidence suggests that children utilize interactive media in a manner consistent with their developmental stages. Early elementary school children (stage 3) are less likely, for example, to use the Internet for communicative functions (e.g., chatting, email, etc.) than are stage 4 children. Overall, however, our understanding of the intellectual, emotional, and social consequences of interactive media emerges primarily as speculation.

DIGITAL DIVIDE

Computer-based media and the digitalization of information in general are of great importance for the future. Political, cultural, and economic participation,

jobs, and success in the markets are expected to be dependent on digital media. Thus, to have a chance for good jobs and good lives in the information society, children need media access, adequate media and computer literacy, and the ability to deal with media of the future. Government, administrative units, and other individuals and institutions who have studied the diffusion of media in society have identified a *digital divide* between those who have access to and experience with the digital media (the "haves") and those who lack such access and experience (the "have-nots"). This digital divide is a frontier that can exist both within a culture or nation and between different cultures and nations; for example, the greatest number of people using the Internet and the best infrastructure for digital media are in the northern half of the world, because these technologies are expensive. Empirically, in each nation a great number of people who are already disadvantaged in other ways also are located on the "wrong" side of the respective digital divide, including the elderly, women, the poor, those with little formal education, and members of certain ethnic groups. Thus, the concept of digital divide is a key factor in relations between different cultures and nations, and it is important as a starting point for a discussion of the consequences of the digital media for democracy, culture, and society.

THE THEORETICAL BASE OF THE DIGITAL DIVIDE

The digital divide has been the subject of a considerable amount of empirical research, which has given rise to three basic theories: the theory of diffusion of innovations, the knowledge gap theory, and the theory of media literacy.

The Theory of Diffusion of Innovations

A starting point for understanding the concept of the digital divide can be seen in the theory of diffusion of innovations. This theory describes how innovations with measurable, fixed advantages for those who use them—ranging from new medicines to new media—diffuse in a population. At the beginning, only specific people (called innovators) use an innovation, but then more and more people see its advantage and become users themselves. This process of diffusion ends when all the people are convinced of this advantage and use the innovation. At this point, it is said that the process of diffusion is *saturated.* Thus, an empirically measured digital divide between the haves and have-nots of a population may exist only temporarily, while the diffusion process goes on. Or it may be a stable divide—saturation has taken place, but not everyone uses computers and the Internet. A variety of strategies may be needed to influence the diffusion process, as, for example, when governments want to hasten the spread of computer access and literacy.

The Knowledge Gap Theory

The second theoretical approach of importance to the concept of a digital divide is the so-called knowledge gap theory. This approach emerged in the context of the campaign analysis. Empirical studies showed that the availability of information in the mass media may enlarge a gap between those who know and those who do not know about the goals of the campaign, because people of higher socioeconomic status get information more quickly than those of lower socioeconomic status. Thus, for example, relevant background information reaches less educated people and those who usually get their information from television more slowly than it reaches those with more education and those who read newspapers. This phenomenon is referred to as the *knowledge gap*, and by analogy the term now is applied to the differences in access to and use of personal computers and the Internet. However, the mechanisms behind those two "gaps" are different—the original knowledge gap referred to information distributed through a variety of media, whereas the digital divide is concerned only with access to and use of computers and the Internet.

Media Literacy

Third, the concept of *media literacy* is of importance for the digital divide concept. As noted earlier, the theory of diffusion of innovations starts with the assumption that it makes sense for a person to use an innovation because of its advantage. If a person nevertheless does not use it and does not want to do so, he or she is not behaving in a rational way, according to media literacy theory. Perhaps there are traditions that prevent him or her from using it, or maybe it is too expensive. In the case of the digital divide, it is usually assumed that nonusers lack media knowledge. To overcome this digital divide, media literacy is taught in schools, in public libraries, and also in other institutions for adult learners, such as community and senior centers.

On the basis of these three theories, much empirical research has been done on the digital divide and its development. These studies mostly measure whether people have access to a computer, to the Internet, or to neither. Only a minority of researchers operate with more complex concepts and try to define the digital divide in terms of the purposes for which people use PCs or the Internet.

DISCUSSION

Although the digital divide between the haves and have-nots demands the attention of government and civil society, the theoretical analysis and empirical research on this divide raise additional issues. First, mere access to a PC or the Internet is not the only factor important for adequate life chances in the upcoming information society—a boy who has access but is just playing computer games all day is probably not well prepared for a good job in the future. Second, the claim of the theory of diffusion of innovations—that an innovation must have a clear and fixed advantage for those who use it—is problematic. Media are not merely technical inventions but also communication potentials that may be used by people in very different ways. Thus, the possibilities offered by the computer or the Internet vary over time and are not fixed. Third, media cannot be understood independently of culture, and so the diffusion theory, which claims to be valid in every culture, is not adequate for the problem. Fourth, the concept of media literacy has ideological implications and must be analyzed in more detail. No one can tell us today what a child must learn to have a good chance in the upcoming information society, but it is clear that mere use of a PC and familiarity with Microsoft products are not enough.

DIGITAL LITERACY

As large-scale studies of Internet use in the United States make clear, young people's Internet use is on the rise. Adolescents, in particular, are turning to the Internet for a wide range of reading and writing purposes. Having conducted an extensive study of Internet use among 9-to-19-year-olds in the United Kingdom, Sonia Livingstone and Magdelina Bober found that young people prefer to use the Internet for communication rather than for information. Yet, as scholars of literacy technologies have pointed out, the technological focus in schools has been geared toward the information component of digital technologies rather than the communication component. This incongruity suggests that, to better understand young people's literacy practices in digital spheres, researchers need to focus attention on the user (reader and writer) of digital texts. In recent studies of digital literacy practices among adolescents, this focus has produced findings related to why many young people choose to read and write online for hours every day and what these online reading and writing practices can tell us about the changing nature of literacy.

When users engage in digital literacy, the distance between the text and the user is minimized. A prominent feature of online reading and writing is interactivity, with reader, writer, and text merging in a fast-paced exchange of words in print—words to be encoded, decoded, interpreted, invented, revised, inflected, and so on, moment to moment. Add to this drama the incorporation of graphical elements, such as photo and video-streaming, emoticons, color, and font variations, and we can begin to imagine the active involvement of the user.

Several recent studies of adolescents' Internet communication have found that, to be a proficient communicator on the Internet, one must "perform" a version of oneself, shifting voices moment by moment for many audiences at once. For writers in digital environments, discerning expectations and social codes can be complicated. To manage the task, users must draw on the intertextual chains that exist through the textual history of each exchange and the larger social and textual network on- and offline. Several studies report that adolescents make conscious linguistic choices in order to perform identities online. Studies of adolescents' uses of text messaging found that users presented themselves differently as they shifted from window to window, taking on different roles almost simultaneously. The enactment of these multiple identities calls into question what it means to have an authentic or personal voice as a writer. Envisioning voice as "authentic" privileges stability across texts rather than the dynamic, fluid concept of voice exhibited by digital writers as they enact identities that depend upon a running analysis of complicated online and offline contexts.

Adolescents have been found to demonstrate numerous literacy skills as they engage in online writing. For instance, they are acutely aware of the various audiences they address, adapting their subject matter and writing styles accordingly, and they critically analyze online texts in terms of the rhetorical context within which the texts are framed. More studies of online reading and writing will help us understand the literacy practices of young people, both in terms of how online reading and writing foster traditional literacy skills and in terms of how online reading and writing create a new set of practices and skills that are changing the face of literacy for the future.

DISNEY

From its origins in the 1920s as a cartoon network, the Walt Disney Company has become one of the five biggest media groups of the world, with products ranging from movies, television shows, and other media programming to a global network of theme parks and a variety of consumer products. In 2004, the company's revenues were a record $30.752 billion. Disney's activities are concentrated in the fields of family entertainment and sports. The company tries to use every possible distribution channel to reach consumers. A main reason for the company's success is its enormous marketing power; nearly all content can be presented through a wide variety of communication channels. Another important reason is the power of the Disney brand, which is well known to families in America, Europe, and Asia as a sign of family entertainment. As a result of the ongoing process of media concentration, the company has the power to present a nearly complete media menu for families.

The most important stockholders are members of the Disney family (who own less than 5%), Sid Richardson Bass, Lee Marshall Bass, Perry Richardson Bass (together about 4%), Berkshire Hathaway, Capital Group, Inc., and members of the Disney management.

HISTORY

The history of this enterprise began in 1923, when 21-year-old Walter (Walt) Disney and his brother Roy founded the Disney Brothers Cartoon Studio in a back room in Hollywood. In 1926, the enterprise changed its name to Walt Disney Studios. In 1928, the first Mickey Mouse cartoon, *Steamboat Willie*, came to the cinema. Since then, Mickey Mouse has been inseparable from the Disney name. The company has a plethora of figures in the movies and on TV, but Mickey is Disney's most important character as well as the most important landmark in the development of the media merchandising and licensing business.

In the company's first decades, a number of other characters helped drive its economic development. Many were found in movies based on fairy tales, such as *Snow White and the Seven Dwarfs*, *Pinocchio*, and *Bambi*. When Disneyland, the company's first amusement park, opened in California in 1955, its main attractions were the numerous and by-then-famous film heroes. The combination of an amusement park with characters and shows for children was quite innovative. Since the 1950s, the national television network ABC has brought the show *Disneyland* to children across the United States. The *Mickey Mouse Club* portion of the program was Disney's first foray into television programming that utilized the Disney brand. In the show's 4-year run, more than 360 episodes were made. The show then returned twice to the screen, first in 1977 for 2 years as a less-successful syndication show, and then in 1989 as *MMC* on the Disney Channel. After a 7-year run, the show ended in 1996. Popular former Mouseketeers from this last period are Christina Aguilera and Britney Spears. In the following years, the Disney brand was built up to become one of the most popular brands in family entertainment worldwide. It was used for nearly every one of the company's products.

The Disney enterprise grew continuously in the 1960s and 1970s but was active almost exclusively in the United States. During this period, Disney Studios produced a number of popular, successful movies. In the 1980s, however, Disney began to suffer; there were no notable new film successes, and Disney stock dropped. In particular, the new trend of computer-animated movies cost Disney its leading position in family entertainment. The company was revived, however, as new investors and new management initiated renovation and restructuring, which brought the enterprise to its present size. New partnerships were made with Pixar and Miramax. The success of Pixar's movies especially helped reinstall Disney as the leader in family entertainment.

The most spectacular takeover in this expansion process was the acquisition of the Capital Cities/ABC Group in 1997. This step cost $19 billion and gave Disney control of a huge number of television broadcasting stations. In 2001, the group acquired the Fox Family Network for $5.3 billion and, along with it, a number of family programs and children's programs previously owned by media moguls Rupert Murdoch and Chaim Saban.

With these acquisitions, the enterprise further secured its already-comfortable market position in the area of children's and family television. Today, this new part of the Disney empire is called JETIX.

Disney was somewhat less successful in its initial online endeavors. The bundle of online activities that were originally a part of the company's Go.com enterprise were restructured after 2000 and are now handled independently. Still, Disney is becoming more and more successful in the online arena, for example, with the online game *Toontown.com* in the United States, Japan, and Great Britain. It is also increasingly involved in the computer and video game market.

THE COMPANY TODAY

In 2005, Michael Eisner stepped down as CEO of Disney, with Robert Iger taking his place. The reason for this change was disagreement between Eisner and the owners, especially members of the Disney family, about the future of the company. In his last years as CEO, Eisner broke off the successful joint ventures with Pixar and Miramax. Disney has subsequently attempted to reestablish cooperation with the two companies and at this writing is in the process of buying Pixar for $4.7 billion.

Today, the enterprise is divided into four areas: Parks and Resorts, Studio Entertainment, Consumer Products, and Media Networks.

Parks and Resorts

Parks and Resorts was established as its own division in 1952 with the birth of Disneyland. Today, there are 11 entertainment parks on 3 continents; the newest park was begun in 2005 in Hong Kong. Besides the

theme parks, a cruise line, various restaurants, sports sites, and a hockey team are part of this division. The segment's revenues were $7.75 billion in 2004, and the operating income was $1.12 billion.

Studio Entertainment

All activities that deal with the production, distribution, and evaluation of films fall into the Studio Entertainment Division. The studios are Walt Disney Feature Animation, DisneyToon Studios, Hollywood Pictures, and Dimension Film. For the films produced in cooperation with Pixar and Miramax, Disney took charge of marketing and distribution. National and international distribution of Disney films is carried out by the Buena Vista Group. In addition, Buena Vista Home Entertainment and Buena Vista Home Entertainment International distribute Disney movies on video and DVD to home entertainment markets worldwide. However, the Buena Vista group does not work exclusively for Disney. In addition to Disney's motion picture endeavors, four music labels belong to the Studio Entertainment Division. Disney movie soundtracks are published by the Buena Vista Music Group. Disney also counts as part of its empire one of the biggest producers of Broadway musicals, Buena Vista Theatrical Productions. *The Lion King* is one of this group's biggest successes. The revenues of the Studio Entertainment Group in 2004 were $8.71 billion, and its operating income was $662 million.

Consumer Products

Under the umbrella of the Disney brand are a plethora of products, including toys, electronic games, books, electronics, food, and beverages. Disney is the largest licensor in the world. The company licenses the Walt Disney name and characters from movies and TV shows to manufacturers, retailers, show promoters, and publishers throughout the world. Disney has also sold the Disney Stores to The Children's Place (TCP), which uses the brand with a license.

Disney is the world's most important international publisher for children; comics with Disney-licensed characters such Mickey Mouse are sold nearly worldwide. Also under the Disney brand are products such as the electronic games made by Buena Vista Games. Publishing houses such as Hyperion Books and Disney Press are part of this segment of the company, as are direct marketing activities. Its revenues in 2004 were $2.51 billion, and its operating income was $534 million.

Media Networks

This is the most important part of the Disney empire. In this segment, we find activities in cable, television, radio, and the Internet. ABC Entertainment, ABC Daytime, ABC News, ABC Kids, and the production company Touchstone Television form the ABC Television Network. Recently, ABC has been very successful with programs such as *Lost* and *Desperate Housewives*. *Desperate Housewives* was produced by Touchstone Television, which has been successful throughout its 20-year history with series such as *Scrubs*, *8 Simple Rules,* and *Monk*. As a part of ABC, ABC Sports presents events such NBA basketball, tennis, figure skating, football, and motor sports. The flagship program of ABC News, *World News Tonight*, is one of the most important news shows in the United States. *ABC Kids* is also a popular show; it airs on Saturday mornings and combines content from the Disney Channel with programming from JETIX and Toon Disney.

ABC Television is the owner of 10 television stations in important markets in the United States. In addition to ABC's television activities, ABC Radio owns 71 radio stations around the country.

Disney is also active in cable TV; its cable networks include ABC Family, the Disney Channel, Toon Disney, SOAPnet, and ESPN. ABC Family can be seen in 88 million homes and is ad supported. The Disney Channel is also a success; it is available in more than 85 million households in the United States, and there are now 22 Disney Channels worldwide. Another channel for young people is Toon Disney, which has an integrated programming block from JETIX. It is available in more than 47 million homes. The channel SOAPnet is the only channel in the United States that specializes in soaps. Many of the viewers in the nearly 40 million homes that receive the channel are women between the ages of 18 and 49.

The second big segment of cable activities is ESPN. Under the name ESPN are more than 50 business entities that specialize in sports entertainment. The ESPN empire is immense and includes the ESPN cable channel (which can be seen in more than

90 million homes), magazines, radio stations, a wide variety of specialized channels, international activities in 12 languages, and 30 separate networks. ESPN is clearly a global titan in the sports entertainment market.

Besides these TV activities, the Media Networks division includes program producers such as Walt Disney Television Animation and JETIX. Buena Vista Television and Buena Vista Television International distribute the programs in U.S. and international markets. The Disney Internet Group, which operates most of Disney's online business, is also part of this segment.

The revenues of Media Networks in 2004 were $11.78 billion, including $6.41 billion from the cable networks and $5.37 billion from broadcasting. The cable activities were especially lucrative; the operating income in broadcasting was only $245 million, whereas in cable it was $1.92 billion.

THE FUTURE OF DISNEY

In the future, Disney plans to expand outside of America, especially in Eastern Europe and Asia. The new theme park in Hong Kong is a step into the Chinese market—a very attractive one for Disney. However, problems stem from the company's American roots. In 2004, $24.01 billion of its revenues came from the United States, $4.72 billion from Europe, $1.55 billion from Asia, and $472 million from the rest of the world. The big question is whether the content of a conservative, traditional, American company will be accepted in the new markets. There were difficulties in establishing the theme park Euro Disney in France, yet the Disney park in Japan was a big success.

Another driver of ongoing growth should be the engagement of the company in new markets, such as interactive entertainment, the Internet, and the production and distribution of digital television; ESPN already sends parts of its content in HDTV.

DISPLACEMENT EFFECT

Archimedes' principle (circa 240 BC) states that "an object immersed in a fluid experiences a buoyant force that is equal in magnitude to the force of gravity on the displaced fluid." In other words, when a person enters a full bathtub, water is displaced onto the floor. This *displacement effect* does not apply only in physics, however. It is also a well-known principle of media effects on children and adolescents. Time spent with media potentially *displaces* other, more active pursuits, such as reading, playing outside, talking with friends, or engaging in sports.

Are there data to support the existence of a displacement effect for media use? Good data exist that document the extent of media use among young people, and additional data show that media use could well have an impact on other activities. A Kaiser Family Foundation report examined the media habits of 2,032 3rd-through-12th-graders nationwide. On average, the children and teens spent nearly 6 ½ hours a day with a variety of media, with TV predominating at all ages. The amount of time spent reading books, however, was a mere 23 minutes a day. Time spent with media dwarfed all other activities, including hanging out with friends (2:16), physical activity (1:25) and homework (0:50). Young people who had TV sets in their own bedrooms were more likely to watch more TV per day (3:31 vs. 2:04) and less likely to read (0:38 vs. 0:54). However, the Kaiser researchers find no difference in physical activity between frequent and light viewers of TV or between those who spent the most time with media and those who spent the least. Indeed, although the association between TV viewing and obesity is becoming well established in the communications and pediatrics research, the possible association between TV viewing and physical activity remains less clear.

This study of older children contrasts with a study of very young children: 1,000 children, ages 6 months to 6 years, conducted by the Kaiser Family Foundation in 2003. In that study, children 6 years and under were found to spend about 2 hours a day with media, which was about the same amount of time they spent playing outside but three times as much as they spent reading or being read to. However, in that study, 4-to-6-year-olds who were heavy TV viewers were shown to spend less time playing outside or reading than their peers who viewed less TV.

Clearly, if older children and teens are spending more than 6 hours a day with media, other activities have to be curtailed. Hence, the American Academy of Pediatrics recommended in 1999 that *all* screen time be limited to no more than 2 hours per day for young people and that children under the age of 2 should not be routinely allowed to watch TV.

DIVIDED ATTENTION, PARALLEL PROCESSING AND

Divided attention (also known as *dual attention*) refers to a person's ability to split his or her attention between one or more different things simultaneously, such as cooking and watching TV. *Parallel processing* involves a person's ability to process information coming from different sources simultaneously. If a child looks at the clock while watching TV in order to answer a parent's question about how long until the show is over, the child is parallel processing the show on TV, the request for information, and the calculation of how long until show is over. Media scholars are interested in divided attention and parallel processing to better understand how children and adults process media messages. In addition, much of this research is concerned with designing better educational programming for children.

When a child watches television, he or she has a lot to do. First, several things may be occurring on the screen. For example, when a child watches *Sesame Street*, the Count von Count character may be counting bats while the number 7 appears on the screen and a news flash scrolls across the bottom of the screen. The child may focus on the Count, the bats being counted, the number 7, or the words scrolling across the screen. The child is also listening to the sound track for the show, which may include the Count's counting, the bats squeaking, and music. Further, the child must integrate the visual and auditory components of the television story into a coherent understanding of what is occurring on screen. In addition, there may be myriad things for the child to pay attention to in the larger environment, such as toys in the room, siblings who are running around, and parents yelling from the next room. Likewise, there are tactile sensations, such as the hardness or softness of the chair the child is sitting on, and there may be odors, such as the smell of cookies baking.

Clearly, the child cannot pay attention to all these various items in the environment. To how many things can a person attend at the same time? Theories of cognition address this question by examining the capacity of the cognitive system. The perceptual and cognitive systems are not capable of processing all the various stimuli in the environment, and introspection tells us that we are good at narrowing our attention to specific items. Most models of cognition posit the existence of working memory. *Working memory* is one's active processing of information relevant to what one is thinking about (e.g., the Count, the bats being counted, the number 7, and the smell of cookies baking in the next room). Some of the processing may be conscious, but much of the activity in working memory is unconscious. Most important, working memory is limited in what it can do at any point in time; there is only so much that a person can think about at a given point.

Because of the limitations of working memory, children must learn to attend to relevant things in their environment and to ignore other things that are not relevant to what they are doing. Of course, children

also learn to divide their attention. For example, the child may be primarily focusing on the Count and the bats that are being counted. But the child may also be aware of the baking cookies, so his or her attention may be divided between these two tasks—understanding what is going on on the screen and determining when the cookies will be ready to eat.

Media researchers study the ability of children to divide their attention in order to better understand how much of the capacity of working memory is occupied by a particular task. Typically, media researchers use a *secondary task* to study the capacity of working memory. That is, a child may have a primary task, such as watching the Count count bats; but the child also has a secondary task, such as counting backward by 1 or 3 or noticing whenever a light flashes on top of the TV. The child's performance on these secondary tasks (how well the child counts backward or how long it takes the child to indicate that the light flashed) is used to measure how well the child can divide attention between the primary task and the secondary task. When a child performs less well on the secondary task, researchers infer that the primary task requires more capacity of the working memory. A demanding primary task leaves less capacity with which the child can perform the secondary task. For this reason, the child's performance on the secondary task is poorer when the primary task is a demanding one than when the primary task is less demanding.

It is important to understand how much of the capacity of working memory is used by a particular task to determine whether people can adequately process the information in the environment. For example, if an educational program required more working memory capacity to process it than young children have, then the show would not help children learn, because their working memories would be overwhelmed. Knowing this information, the producer of the program could simplify the segment or present the information more slowly to enable the children to process the necessary information in working memory. In addition, by studying the capacity of working memory, researchers understand better how to improve the efficiency of working memory so that children can process more information.

Many factors influence the capacity of working memory. For example, the more children know about a particular topic, the more efficiently they can process information in working memory. Children who are just learning to count must dedicate more of the capacity of working memory to counting along with the Count than must children who learned to count several years ago. The better children understand the narrative structure of a story or the formal features of TV (such as cuts, edits, zooms, and so forth), the more efficiently they can process information presented in the media.

Research has demonstrated that people can become more efficient in how they perform tasks in working memory. For example, when a child first learns to read, working memory can be taxed just trying to figure out how to sound out a word and then figuring out what the word means. However, as the child reads more and more, it becomes easier to identify the word on the page. With enough practice, word recognition becomes so automatic that it takes no effort at all to see the word on a page. The process of reading has changed from a controlled process that is effortful and takes capacity in working memory to an automatic process that uses none of the capacity of working memory. *Parallel processing* occurs when a task has become so automatic that people can process that task and other tasks at the same time. For example, when a child is first learning to count, counting along with the Count may take up most or all of working memory capacity. With practice, the counting will become automatic such that the child can count along with the Count and in parallel determine when the cookies coming out of the oven will be cool enough to eat.

DRUG USE, DEPICTIONS OF

Illicit drug use in adolescence is associated with myriad adverse outcomes, including delinquency, depression, and violence. By the time adolescents finish high school, 51% of them report having tried an illicit drug. Findings from the Centers for Disease Control and Prevention's 2003 Youth Risk Behavior Survey indicate that 40% of students used marijuana at least once during their lifetimes, 12% used inhalants, 11% used ecstasy, and 9% used cocaine. Trend data from the Monitoring the Future Survey suggest a gradual decline over the past decade in most categories of drug use except inhalants and OxyContin, a highly addictive narcotic. Content analyses provide detailed accounts of what adolescents see and hear about illicit drugs in popular media, but the consequences of exposure to such messages are not well understood.

Although much is known about the portrayal of tobacco and alcohol in popular media, fewer content analyses have examined depictions of other drug use in movies or on television. Illicit drugs appeared in 22% of the 200 most popular movie rentals from 1996 and 1997—in 20% of R-rated and 17% of PG-13 movies. Of the 43 movies in which illicit drugs appeared, 26% contained explicit, graphic portrayals of drug preparation or use. Marijuana was found most frequently (in 51% of the 43 movies), followed by powdered cocaine (in 33% of the 43 movies). At least one major character used illicit drugs in 69% of the scenes of that portrayed drug use. Few movies portrayed the negative consequences of drug use or emphasized its illegal nature; only 28% of the 43 movies in which illicit drugs appeared associated these substances with crime or violence.

A study of 87 top-grossing movies of all time observed marijuana use in 8% and noninjected drug use in 7% of the movies. Drug use in these movies was typically portrayed by adult characters who were not in main roles. No illicit drugs appeared in any of the 81 G-rated movies released between 1937 and 2000, although three movies showed characters consuming a food, pill, or potion that transformed them, and two movies showed a syringe being used.

Television is often identified as adolescents' primary source of information about illicit drugs, but little is known about how entertainment television depicts drug use. A study by Peter Christenson and his colleagues concluded that prime-time television more often talks about than shows illicit drugs: They were mentioned in 21% and seen in 4% of the situation comedies and serial dramas most popular with adolescents. Half of the episodes that contained drug references included humorous statements about drug use, such as jokes about smoking marijuana or attending drug rehab. Almost as many episodes included at least one negative statement about drug use, such as warning characters to avoid drug use or information about its harmful effects. Most episodes that depicted drug use also portrayed at least one negative consequence, such as a dangerous health outcome, arrest, or losing a coveted job.

Another study observed that illicit drug use was less prevalent on prime-time television than in real life: incidence rates were 1.5% among main characters, 0.8% among all characters combined, and 6.1% among the U.S. population. Compared to drug users in the U.S. population, however, drug users on TV were more likely to be minority than white.

Most evidence about the relationship between illicit drug use and media exposure focuses on adolescent preferences for different types of popular music. The perception that some music subcultures promote drug use dates back at least as far the association of jazz and cocaine in the 1920s. A study of the frequency and nature of drug references in popular music analyzed 1,000 songs from five genres: alternative rock, country and Western, Hot-100, heavy metal, and rap. Illicit drugs were mentioned in 18% of the songs but much more often in rap lyrics (63%) than in the lyrics from other categories. A companion study of 258 music videos from three popular cable channels found that illicit drugs were mentioned in 20% and seen in 3% of the videos. Mainstream and modern rock videos were more likely to show illicit drug use than were rap and hip hop videos or other genres. In samples of both music lyrics and music videos, marijuana was the substance mentioned most frequently, followed by powder and crack cocaine.

Correlational studies confirm disproportionately higher rates of self-reported drug use among fans of heavy metal and rave music but not among fans of rap music. Subcultural music preferences predicted all illegal drug use patterns reported by a sample of more than 10,000 Norwegian 14-to-17-year-olds. Students who liked Seattle grunge rock were almost twice as likely to report using marijuana and amphetamines as other students. Liking house techno music was associated with a two- to threefold increase in the odds of

using ecstasy (MDMA) only, and using ecstasy and amphetamines. Adolescents who had never used illegal drugs reported significantly less interest in all kinds of music studied (house/techno, Seattle/grunge, acid jazz, and new age).

Longitudinal research is needed to permit causal inferences about media effects on adolescent drug use and to provide a closer examination of characteristics that may explain why adolescents who favor particular types of music are also more likely to use illicit drugs. Keith Roe coined the term *media delinquency* to refer to adolescents' affinity for what he calls "disvalued" media and other forms of delinquency, including illicit drug use. Other researchers emphasize the role of sensation seeking, a preference for exciting experiences and stimuli. It would be helpful to examine the individual differences that predict which adolescents "see" and "hear" references to illicit drugs in entertainment media. In addition, research is needed to understand how adolescents interpret such portrayals and the consequences for their attitudes and behaviors regarding drug use.

EATING DISORDERS

Over the past few decades, the prevalence of eating disorders has steadily risen among adolescent girls. Although there are several causes of eating disorders, many point to the media's constant portrayal of the ultra-thin female body as normal, attainable, and ideal as one of the greatest contributors. These media models weigh 23% less than the average woman and fit the established weight criteria for anorexia, making their body types unrealistic and unhealthy. Ample research suggests a relationship between media exposure and eating disorders; however, many have theorized that this relationship holds only if girls internalize the thin-body ideal and compare themselves to thin media models. This entry discusses internalization, comparison, and the direct relationship between media and eating disorder relationships.

Of the 1% to 10% of the population suffering from anorexia and bulimia, 85% to 95% are female, usually aged 15 to 19. Anorexia ranks third in chronic illnesses among adolescent females. Furthermore, many adolescent girls have disordered eating patterns, meaning they use unhealthy weight control methods but do not have a full-blown eating disorder. For example, one study found that 11% of teen girls vomited, 8% used diet pills, and 7% used laxatives to lose weight. Compared to females, the 1 million males suffering from eating disorders, mostly binge eating, is relatively small but on the rise. Studies of adolescents, media, and eating disorders concentrate on females almost exclusively. Males are studied in the context of developing body dysmorphic disorders rather than eating disorders.

INTERNALIZATION OF THE ULTRA-THIN BODY

Adolescents have a high degree of exposure to media, with 80% reading magazines for at least 4 hours a week and the average girl watching 3 to 4 hours of television every day. These media promote the ultra-thin body ideal as desirable and attainable by using primarily ultra-thin models and female TV characters, printing abundant dieting articles and ads, and printing fitness articles that focus on weight loss or attractiveness.

Adolescents internalize these messages about thinness. Some studies have found that adolescent girls describe their ideal body types as similar to media models—tall and extremely thin—and rate borderline anorexic bodies as extremely attractive. Others have found that media exposure explained one third of the variation in high school girls' belief in the ultra-thin ideal and that frequent readers of fashion magazines were twice as likely to have dieted and three times as likely to have exercised to lose weight. Moreover, the degree to which girls internalize the thin ideal has been associated with eating disorders.

SOCIAL COMPARISON AND INTERPERSONAL ATTRACTION

Research also suggests that comparison with media models links media exposure to disordered eating. This association occurs when adolescents want to look like media models and compare themselves with models, and several studies support this assertion. Studies have found that older adolescents with eating disorders were significantly more influenced by

media and more likely to compare their bodies with media models and celebrities than those without eating disorders. Female adolescents without eating disorders tended to compare themselves with friends more often than with portrayals in media. Other studies of adolescents have found that attempts to emulate media personalities predicted bulimic behaviors, which might explain why many anorexics and bulimics have said that fashion models motivated and guided their desire to be thin.

DIRECT RELATIONSHIP BETWEEN MEDIA AND EATING DISORDERS

Many studies have found direct relationships between eating disorders and media exposure. These studies fall into three categories: exposure to print media, exposure to TV, and both TV and print media exposure.

The evidence suggests that print media are related to eating disorders. For example, Michael Levine and colleagues found that magazine ads and articles influenced middle school girls' ideal body shapes and their motivation to attain those ideals, and the influence of these magazines was highly associated with disordered eating, explaining 35% of the differences among the girls' disordered eating scores.

Comparisons of different magazine genres have shown that reading beauty and fashion magazines as well as fitness magazines is related to eating disorders, but one study found that reading fitness magazines was the best predictor of eating disorders even after taking into account interest in fitness and dieting topics. As for reading sports magazines, the more adolescents read sports magazines, the less likely they are to have bulimic symptoms; however, no relationship between sports magazines and anorexia has been shown.

Kristen Harrison conducted studies with preadolescents and adolescents and found that their TV viewing predicted eating disorders. Moreover, a 1995 study by Anne Becker found that, prior to television's introduction to Fiji in 1995, Fijians endorsed a plump body ideal. However, 38 months after television was introduced in Fiji, 74% of the girls reported feeling "too big or fat," 15% vomited to control their weight, and eating disorders suddenly increased.

Finally, some studies have looked at TV and print media exposure together. Eric Stice and colleagues found a direct relationship between media exposure and eating disorders, and media exposure explained 43.5% of the eating disorder symptom differences among adolescent females. Other studies have found that magazine reading predicts eating disorders, whereas TV viewing does not. Moreover, girls who have more eating disorder symptoms tend to increase their fashion magazine reading but decrease their television viewing.

SHIELDING CHILDREN AND ADOLESCENTS FROM HARM

Although a large amount of research indicates a link between media exposure and eating disorders, many still debate how much influence the media actually have, given the number of people exposed to media and the number that actually develop an eating disorder. Most agree, at the very least, that the media contribute to the thinness obsession and tell us that thinness is beautiful and good.

To overcome or at least diminish media's potential influence, health experts suggest teaching children to be critical of media images—for example, talking to children about how computers are used to make models appear thin and erase skin rolls, and how sometimes computers are used to combine body parts from different models to create the "perfect" model.

EATING HABITS, MEDIA INFLUENCE ON

The eating habits of children today are quite different from the consumption patterns of their peers of past generations. Baby boomers experienced "new" foods such as frozen meals, sugar-laden snacks, and food options containing large amounts of preservatives. Generation X-ers were often challenged to "fend for themselves" by making their own meals because their parents were at work. Obesity figures for the current youth generation are bleak. The American Academy of Pediatrics estimates that one in every four children under the age of 12 is considered overweight or obese—an astonishing increase of 50% in the past 30 years. Critics cite a combination of poor eating habits, lack of exercise, and lifestyle (including media use) that has exacerbated the situation. Labeling today's children as "Generation Extra Large," Lisa Tartamella, Elaine Herscher, and Chris Woolston noted that this rapidly growing epidemic continues to spread among our nation's children.

EATING HABITS

According to the U.S. Census Bureau, 5-to-11-year-olds account for roughly 27 million of the nation's population. American youth are becoming consumers at younger ages. Estimates show that children in this group will directly spend or influence parents to spend approximately $5.8 billion on food and beverages in 2005, which is almost 30% of the total expenditures for these items. Children's eating patterns have changed significantly over the past two decades as well. Children are now eating more often; they are more often eating away from the home; and they are consuming more fast food. Most children do not eat according to federal dietary guidelines.

Changes in the American family structure play a key role in food consumption, with more mothers joining the workforce and children and teens gaining more power in the household decision-making process. Other notable influences include peer influence, ethnicity, the overall school environment, and commercialism starting at a very early age. Children often have poor consumer decision-making skills, which can contribute to early formation of seriously unhealthy nutritional patterns. Results of a 1998 *USA Weekend* Roper Report show that 78% of youth influence where the family goes for fast food, 55% choose the restaurant for dinner, and 31% determine specific brands that families purchase. Parents cite two overwhelming barriers to preparing a healthy family meal: (1) different food preferences of family members and (2) children's desire to eat advertised foods. The Center for Science in the Public Interest has argued that growing health problems such as unhealthy diets and childhood obesity can be linked to the advertising of high-fat, high-sugar food products targeting children.

MEDIA INFLUENCE

Research has shown that media influence is a strong predictor of children's food consumption, and Kristen Harrison and Amy L. Marske noted that sweets, snack foods, convenience foods, and fast foods totally dominate the ads children see. Food advertisements and children's use of television, movies, video games, and the Internet as entertainment outlets for hours each day have been blamed for poor nutrition and heavier children in today's society. The ever-expanding world of media gives marketers even more opportunities to target youth.

Children are inundated with food marketing on a daily basis, and major food retailers often target them via highly specialized advertising. In the overall American economy, U.S. food products accounted for $7.3 billion in advertising expenditures at the turn of the 21st century. as a comparative yardstick, the U.S. Department of Agriculture spends roughly $333 million per year on nutritional education, whereas the total U.S. advertising industry expenditure for confectionary and snacks alone is approximately $1 billion. By targeting youth from an early age, food companies are able to build positive, long-lasting brand relationships and create brand loyalty among children, teens, and parents.

Despite a plethora of new media options, television remains the medium most widely used to reach children. Today's child views approximately 60,000 commercials a year. Content analyses show that food

is the most frequently advertised product category on children's television. The majority of food advertisements feature products high in sugar (such as cereal, candy, and snack foods), and in recent years an upswing in the frequency of fast-food commercials has been documented. Children seem to choose food based on exposure, and greater television use is associated with higher intake of energy, fat, sweet and salty snacks, and carbonated beverages, and with lower consumptions of fruit and vegetables.

Recent trends in marketing food to young people focus on merging entertainment and advertising. Children's magazines often feature puzzles or games in advertisements. Product placements in video games, television shows, and movies are increasingly common. Associating toys and apparel with food brands or spokescharacters increases children's awareness of products. Corporate websites allow children to play games, color pictures, and register to win free promotional items, many times after the child first provides contact information for database and direct marketing purposes. Schools are filled with food marketing, from textbooks sponsored by companies to fast-food outlets in cafeterias to unhealthy food ads on Channel One. The media possibilities geared toward reaching children today are almost endless.

THE FUTURE

Most scholars agree that media influence the eating habits of children. They also cite the complexities of other cultural factors, such as parental communication and sedentary lifestyles, as important factors in the obesity epidemic. Food is used for much more than essential body energy. Some parents and teachers bribe children with food, sometimes using candy and sodas as rewards for good behavior. Parents impose excessively stringent and unhealthy weight loss programs on their children, often increasing the chances of children perceiving themselves as "needing" to diet.

A recent Institute of Medicine report suggested several important steps in correcting media's influence on childhood food consumption. Possible areas for improvement included decreasing food advertisements targeting children, especially children 8 years and younger who do not have the cognitive skills necessary to recognize persuasive intent; increasing mass media educational efforts; and promoting physical activity through public relations campaigns. Parents can also help children develop strong consumer decision-making skills from an early age to help counteract food marketers' influence on purchase.

E-COMMERCE

E-commerce, defined as economic transactions (and related activities) conducted using networked communications technologies such as the Internet, has transformed the global economic landscape. E-commerce primarily consists of four different categories: business-to-business (B2B), business-to-consumer (B2C), consumer-to-consumer (C2C), and consumer-to-business (C2B). Although attention has long focused on the first two categories, technological advancements coupled with entrepreneurial spirit have seen C2C make headway in recent years, as witnessed by the popularity—and profitability—of ventures such as eBay. Although the early years of e-commerce was characterized by the dot-com craze, the subsequent dot-com bust has shown that the success of an e-venture is probably contingent on innovativeness augmented by a sound business model and tempered by caution. Regardless of the sobering

lessons from the early years, e-commerce is here to stay, as evidenced by both the number of online users who indulge in commercial transactions as well as the sheer volume of financial activity. Several surveys indicate that more than 100 million Web users shop online, with total e-commerce transactions expected to reach $316 billion in 2010, according to a report from Forrester Research available at www.shop.org, an online association for retailers.

Given the number of teenagers and young adults who have assimilated the Internet into their everyday lives, it is not surprising that marketers and advertisers have identified this group as an influential segment in dictating their marketing decisions. Some survey data from Harris Interactive suggests that online spending by members of Generation Y (8 to 21 years old) ranges in the billions of dollars, and online spending among 18-to-24-year-olds is four times as much as online spending by adults (see shop.org). Other reports suggest that teens and young adults' online spending was expected to touch the $5 billion mark in 2005, and that their online research influenced more than $20 billion in offline spending. Indeed, by 2008 the typical teenager is expected to spend approximately $400 in online purchases annually. Teenagers are reported to be especially influential in purchasing decisions pertaining to consumer electronics and music.

Several e-retailers have realized the importance of the youth market and have attempted to identify specific themes that most appeal to this segment. Industry experts deem several factors to be critical to tapping the youth market. Suggestions range from developing separate websites for young and adult audiences—as already practiced by such outlets as Macy's and Pottery Barn—as well as marketing to these audiences in venues that are most likely to draw them (e.g., social networking sites such as facebook.com). In addition, young audiences are generally known to respond favorably to the deployment of multimedia-enriched features on sites. Finally, both industry-driven beliefs and empirical evidence from academic research indicate that offering customized or personalized products and services—offerings that are delivered based on an individual's unique likes and desires—may well be the next frontier in e-commerce. In terms of barriers to e-commerce among youth, invasion of privacy and lack of access to credit cards may be some of the most important impediments that marketers have to deal with. Nevertheless, with technology advancing at a rapid pace and with a sizable proportion of youngsters spending a substantial amount of time online, this segment will continue to exert a major influence on the continuing evolution of e-commerce.

EDUCATIONAL TELEVISION, EFFECTS OF

Television programs have the potential to educate children in important ways. Carefully designed educational programs can positively influence a child's readiness for school by teaching basic letter and number recognition or more advanced vocabulary and math skills. Television can introduce children to places, cultures, and people that they otherwise may have little or no opportunity to learn about in their everyday lives. In contrast, critics suggest that watching TV contributes to less creativity, shorter attention spans, and increased apathy toward school. This entry defines educational programming and examines the effects of viewing this content.

DEFINITIONS OF EDUCATIONAL PROGRAMMING

Children's educational television programming has been defined generally as programming that is planned around developmental or educational goals. More specifically, educational programs have been designed to teach the academic skills taught in school (e.g., vocabulary, math, science, and geography) or to teach prosocial behaviors (e.g., altruism, self-control, and positive social interactions). Educational programming can also incorporate a broad and varied range of topics, including physical well-being (motor skills and health-related knowledge), social and emotional development (intrapersonal and interpersonal skills), approaches to learning (developing a positive attitude about learning), language skills, cognitive skills (problem solving, reasoning), and knowledge of social and natural sciences.

Policymakers have also provided broad definitions of educational content. In response to the Children's Television Act (CTA) of 1990, the Federal Communications Commission (FCC) defined educational programming as "any television programming that furthers the educational and informational needs of children 16 years of age and under in any respect, including the child's intellectual/cognitive or social/emotional needs" (FCC, 1996). This definition resulted in broadcasters airing programs of questionable educational value. For instance, *The Jetsons* was listed as educational because it taught children about life in the future. Thus, in their attempt to meet the requirements of the CTA of 1990, broadcasters clearly missed the mark. In a subsequent policy known as the three-hour rule, explicit guidelines clarified the frequency and definition of educational television programming for children. The policy mandates that all broadcast stations must air a minimum of three hours of educational children's programming each week for expedited license renewal. Amy Jordan's recent assessment of the three-hour rule indicates that broadcast stations are adhering to this FCC mandate, yet they do not seem to publicize their educational offerings for children.

COGNITIVE PROCESSING OF TV: ATTENTION AND COMPREHENSION

The prerequisites for learning or internalizing the academic or prosocial content presented on television are attention to and comprehension of the educational message. David Bickham, John Wright, and Aletha Huston provide a comprehensive review of the topics of attention and comprehension, specifically highlighting the active and passive models of television viewing. The *passive model* proposes that children's attention and processing are governed by the glitz of the production features or formal features. For instance, perceptually salient features (e.g., rapid movement, lively music, special visual effects, unusual cartoon voices) will attract young children's attention. In contrast, the *active model* proposes that, instead of just capturing children's attention, the formal features help them make their own attentional decisions and viewing choices. Formal features signal whether a program is appropriate for and interesting to them, and children will pay attention to content whenever formal cues indicate that attention is needed. Although perceptually salient features may attract initial attention, comprehensibility determines sustained attention to the program. Therefore, knowledge of the meanings behind formal features is a critical element in developing media literacy or critical viewing skills; moreover, these critical viewing skills need to be developed in order to use television to its full potential.

LEARNING FROM EDUCATIONAL TELEVISION

Academic research on the effects of children's television has focused on total time spent viewing TV as well as time spent viewing specific categories or genres of programming. *Sesame Street*, in particular, has set a standard of excellence for those working in children's educational television. It was the first children's educational program to integrate curriculum into production. The use of Muppets and production techniques from advertising and cartoons created a learning environment that was engaging and fun, as if to "disguise" the educational message.

Sesame Street Research

The Sesame Workshop (which was called the Children's Television Workshop when established in 1968) has embraced both formative and summative research. *Formative research* is conducted to pilot-test new program segments with groups of children from the target audience. These types of studies are usually concerned with children's attention to, understanding of, or interest in new content areas. Furthermore,

formative research can also be used to test new instructional methods or new production techniques. Findings from formative research have resulted in important changes to education programming. For instance, Rodney Dennis explored ways of getting children to actively participate in a game designed to teach them to sort or classify objects. “Sorting” means identifying one of several objects as “not like the others” on some characteristic (e.g., three socks and a shoe). Dennis found that adding a brief pause (1 to 2 seconds) after asking the question increased the likelihood that children would point to one of the objects on the screen. This work also revealed that adding narrative to encourage children to “go ahead and point now” further increased their active participation in the game. These methods designed to facilitate participatory learning are used in many *Sesame Street* bits, as well as in newly developed children’s programming such as *Blue’s Clues* and *Dora the Explorer*.

The Children’s Television Workshop also recognized that assessing the effects of their programming was critical to achieving their goals. They were trying to communicate with an audience of children under the age of 6 who were economically disadvantaged. Specifically, they wanted to use television to teach 4- and 5-year-old children from low-income families the school readiness skills that are related to early success in school. *Summative evaluations* to assess the final product or outcome of *Sesame Street* were conducted in the early 1970s. These evaluations found that regular viewers of the program demonstrated gains in learning letters and numbers as well as other cognitive skills.

Later assessments of *Sesame Street* demonstrated positive influences on children’s development. The Early Window Project, conducted by John Wright and colleagues beginning in 1990, was a 3-year longitudinal study of low- to moderate-income children’s media use and its relationship to the subsequent development of their academic skills, school readiness, and school adjustment. This study of more than 250 families demonstrated that viewing *Sesame Street* at ages 2 and 3 predicted higher scores at age 5 on measures of language, math, and school readiness (e.g., recognizing shapes, colors, and letters). The effects of viewing were independent of parents’ education, income, primary language spoken in the home (English or Spanish), and the overall quality of the home environment as measured by the Caldwell and Bradley Home Observation Measure of the Environment (commonly abbreviated H.O.M.E.).

Longitudinal research also demonstrates that viewing educational content at an early age contributes to positive academic outcomes much later in life. In the Recontact Study, Daniel Anderson and colleagues investigated the long-term relationship between preschool children’s television viewing and their achievement, behavior, and attitudes in adolescence. The researchers interviewed adolescents at ages 15 to 19, many years after they had participated in similar investigations as preschoolers. Adolescents who had been frequent viewers of *Sesame Street* at age 5 had better grades in high school, read more books for pleasure, had higher levels of achievement motivation, and expressed less aggressive attitudes then did adolescents who had rarely viewed the program at age 5.

OTHER EDUCATIONAL RESEARCH AND INITIATIVES

Summative evaluations of other educational television programs have revealed positive effects in multiple domains. Children who watch programs containing prosocial messages may be learning lessons about tolerance, cooperation, or sharing, to name a few possibilities. For instance, research indicated that children learned task persistence, tolerance of delays, rule obedience, and positive values from *Mister Rogers’ Neighborhood,* and learned about friendship and tolerance from *Fat Albert and the Cosby Kids*. Evaluations of *Barney and Friends* suggested that toddlers who viewed Barney showed increases in imaginative play, demonstrated less aggressive behavior, and showed increases in persistence and cooperation, compared to control groups.

Sandra Calvert’s work illustrated that viewers retain information presented in segments of *Schoolhouse Rock* over extended periods of time. Her findings suggested that singing is better for learning information verbatim, whereas spoken information may facilitate a deeper level of processing. Research on *Reading Rainbow* demonstrated that the program has been successful at stimulating children’s interest in reading and their interest in particular books (demonstrated especially by going to the library to check out a book that has just been previewed on the program).

An ongoing concern is the number of children who are unequipped with basic skills when they enter school. Because television is such a pervasive influence, researchers and public policymakers have called upon television to help improve school readiness skills in

preschoolers. Consequently, PBS initiated a *Ready to Learn* series to address the school readiness needs of young children, as well as implementation of an outreach service designed to meet the needs of parents and other caregivers. Programs in this lineup have included *Barney and Friends, Arthur, Mister Rogers' Neighborhood, Sesame Street, Clifford, Teletubbies*, *Postcards from Buster*, and *Between the Lions.* PBS is committed to getting children ready to begin school by offering high-quality programming based on specific educational goals.

CHARACTERISTICS OF EFFECTIVE EDUCATIONAL PROGRAMMING

The substantial body of research on cognitive processing and comprehension of children's educational television programming indicates that there are several key ingredients to effective design, only a few of which have been discussed here. Perceptually salient features and comprehensible language are keys to attracting and maintaining the attention of young viewers. Teaching content during periods of development when children are "ready to learn" those concepts is illustrated within popular preschool programming such as *Sesame Street*. Repetition of concepts (presenting the same concept over and over or presenting the same concept in many different ways) allows for rehearsal and facilitates memory. Finally, children are active learners. Educational programs that offer children the opportunity to interact with the program and subsequently master concepts contributes to learning from television.

EDUCATIONAL TELEVISION, HISTORY OF

Educational and informational programming—defined by the Federal Communications Commission (FCC) in 1996 as "any television programming that furthers the educational and informational needs of children 16 years of age and under in any respect, including children's intellectual/cognitive or social/emotional needs"—has evolved rather dramatically from the 1950s to the present. Today, educational programming offers a rich array of educational opportunities for young viewers that engage them long beyond the duration and confines of the telecasts of traditional television programs.

Don Herbert and a young assistant conduct an experiment on *Watch Mr. Wizard,* a pioneering show in educational television for children. The program aired from 1951 to 1965 on NBC, then returned for a season in 1971. Created and hosted by Herbert, the show aimed to make science applicable to children's everyday experiences, and it often used everyday household items in the demonstrations. *Watch Mr. Wizard* was shown in the classrooms of many schools and spawned thousands of Mr. Wizard Science Clubs in the 1950s and 1960s.

THE ORIGINS OF EDUCATIONAL TELEVISION

The development of educational television was greatly facilitated by a television station license "freeze" between 1948 and 1952, during which the FCC paused during a period of frenzied development in television's early history to engage in a number of important deliberations that would ultimately shape the future of broadcasting. The concept of educational programming was extremely controversial at this time. Commercial broadcasters claimed that the reservation of noncommercial channels was not necessary, because their programs already served the educational needs of the audience. In fact, they argued that broadcasting was too important a resource to entrust to those who had no profit motive to spur the new medium's development. Such an industry view had prevailed during the discussion of public radio leading up to the Communications Act of 1934.

An important "voice crying in the wilderness" played a pivotal role in shifting the ground rules for television away from radio's prevailing model of pure commercialism. Frieda B. Hennock, the first woman FCC Commissioner, argued eloquently and forcefully that 10% of television channels should be reserved for educational television. Thanks to an effective public communication campaign initiated by Commissioner Hennock, when the FCC issued its Sixth Report and Order in April 1952, the license allocation plan included 242 specific channel reservations for non-profit educational licenses.

MAJOR DEVELOPMENTS FROM THE 1950S TO THE 1980S

During 1950s and early 1960s, as educational television stations struggled through a formative period, most of the educational programs introduced for children featured adult "talking heads" addressing child audiences, assorted puppet shows, make-believe vignettes, and other primitive means of instruction and edification. Targeted children's programming, such as *Friendly Giant* and *Tales of Poindexter,* occupied only a minor percentage of programming time on these educational stations, and they were not given much consideration on the emerging state and national educational programming networks.

Educators and the general public were not very satisfied with these early programming developments for children. In response, the Ford Foundation and other philanthropic organizations not only supported capital facility grants to community and educational organizations, which helped dramatically expand the number of educational stations, they also joined with federal education agencies to support a number of remarkable programming initiatives during the late 1960s and throughout the 1970s. As a result, a number of innovative and popular programs were developed and broadcast, including the perennially popular and educationally effective *Sesame Street,* developed by the Children's Television Workshop (CTW, now Sesame Workshop).

CTW programming revolutionized children's educational television, in large part because CTW President Joan Ganz Cooney brought producers, educational advisors, and researchers together to create educational programming. Not only did the CTW team fuse previously independent forces, they programmed

for the developmental level of their programs' targeted audiences, and they harnessed the production capabilities of the television medium to meet specific instructional goals while also addressing critical societal needs, such as getting young children reading for school (e.g., *Sesame Street*), improving the reading skills of school-age children (e.g., *The Electric Company*), and steering girls toward career interests in science (e.g., *3-2-1 Contact*).

Other programming and production companies successfully imitated the program development and production model of CTW and launched noteworthy programs like *Freestyle* and *Vegetable Soup,* essentially turning the late 1960s and the 1970s into the first golden age of children's educational television. This period also featured the evolution of programming from "educational" to "public" television, which culminated in the Public Broadcasting Act of 1967.

The 1980s were to witness a setback in educational programming because of President Ronald Reagan's "marketplace approach" to broadcast regulation, under which the FCC no longer required stations or networks to broadcast children's programming. Only financially secure and extremely popular children's programs, such as *Sesame Street* and *Mister Rogers' Neighborhood,* were to survive in the era of Reaganomics.

THE 1990S AND BEYOND

Three developments revived children's educational programming efforts in the 1990s and through the portals of the 21st century. The first was the Children's Television Act of 1990, through which Congress took a stand to advocate children's rights to educational and instructional programming. The second was the Telecommunications Act of 1996, which reinforced and strengthened the tenets that children's educational programming was a "public good" and specified guidelines for broadcasters to follow regarding educational television. The third was the increased advocacy of the nation's parents, caregivers, and child advocates, which led cable and satellite programming channels such as Nickelodeon (especially their preschool entity, Nick Jr.) and the Disney Channel to effectively create and market curriculum-based programming that could and would be both educationally valid and commercially successful in the new era of narrowcasting and highly targeted programming.

These developments led to a new golden era of children's programming, both on public television in the form of entertaining, enlightening, and educationally viable PBS Kids programs such as *Arthur, Barney, Cyberchase, Dragon Tales,* and *Reading Rainbow,* and on commercial cable channels in the form of *Blue's Clues, Dora the Explorer,* and *Bear in the Big Blue House,* among many others. Most of these highly successful modern programs have the same ingredients that have allowed *Sesame Street* to survive and thrive for more than three decades: developmentally appropriate curricula, effective formative and summative evaluation strategies, high-quality production features, and solid entertainment values. The contemporary successful programs generally target the preschool audience, however, leaving room for improvement in programming targeting older children. Moreover, all the successful programs of this latter golden age have taken full advantage of the contemporary digital environment and the potential of convergence, cross-product promotion, and intermedia marketing to enhance the appeal and value of educational programming in the 21st century.

EDUCATIONAL TELEVISION, PROGRAMMING IN

Commercial television has offered little educational programming for children during most of its history

in the United States. Periodic increases in the quantity of educational children's programs shown on commercial stations have resulted largely from the occasional threat of governmental intervention. Public television, on the other hand, has fostered a sizeable catalog of high-quality children's educational programming, including some of the best-loved and longest-running shows on television. Although the emphasis in much of the early educational programming was on developing cognitive skills, there has been a recent increase in programs intended to develop social and emotional skills and to teach prosocial values such as kindness and respect for others.

EARLY EDUCATIONAL PROGRAMS

Early television in the United States was largely void of programming for children that had a specific educational intent. One notable exception was *Watch Mr. Wizard,* a science show for kids that aired on NBC from 1951 to 1965. It was created and hosted by Don Herbert (a.k.a. "Mr. Wizard") who, with the help of his young assistants, conducted dramatic experiments demonstrating basic principles of natural science. *The Ding Dong School* was another early educational show that premiered in 1952 on NBC. Dr. Frances Horwich, a professor of education, served as the host and encouraged creativity through simple lessons for preschoolers in singing, finger painting, and make-believe. Despite strong ratings and critical acclaim, NBC cancelled the show after 4 years to replace it with more lucrative programming for adults. CBS's most significant contribution to educational programming was *Captain Kangaroo* (1955–1984). Although it was primarily an entertainment show for young children, *Captain Kangaroo* also wove educational themes and positive, "life-oriented" messages into many of the stories, skits, and dialogues with the kindly host (played for nearly 30 years by Bob Keeshan).

Government concern about the quality of television for children spurred networks to increase their informational programming for children in the 1962 television season. Most of these educational shows were short lived, such as NBC's *Exploring* and CBS's *Reading Room.* However, *Discovery,* a documentary-style series that explored different parts of the world, lasted on ABC for 9 years.

PBS REVOLUTIONIZES EDUCATIONAL TELEVISION

Programming for children in the United States made a huge leap forward in 1969 with the debut of the non-commercial, educational Public Broadcasting System. Two of PBS's first offerings, *Mister Rogers' Neighborhood* and *Sesame Street,* revolutionized children's television. Fred Rogers created *Mister Rogers' Neighborhood* (1969–2001) to encourage young children's healthy emotional development. The show featured Rogers conversing directly with his audience about their feelings and experiences, visiting with his neighbors, and sending the child audience to the "Land of Make-Believe," where puppets and cast members explored socioemotional themes. The show's slow pace and Rogers' gentle, low-key style engaged very young children in topics ranging from learning to tie shoes to coping with the loss of a loved one. *Mister Rogers' Neighborhood* remained in production for more than 30 years and continues in syndication on PBS.

Sesame Street (1969–) was created by Joan Ganz Cooney and the Children's Television Workshop (CTW) with $8 million in funding from private foundations and the U.S. Office of Education. Cooney was struck by children's rapt attention to television advertising, and she developed the idea for a show that would apply advertising techniques—such as high levels of activity, jingles, and animation—to "sell" preschoolers on skills that would prepare them for school. In particular, the show sought to advance the school readiness of low-income and minority children.

CTW's production team consisted of experienced entertainment television producers and experts in childhood education. They grounded *Sesame Street* in a curriculum that initially focused on social and affective development as well as preacademic skills in language, numbers, reasoning, and perception. Their groundbreaking approach utilized empirical research to make sure that *Sesame Street* achieved its educational goals. *Sesame Street's* magazine format alternated cartoons, live-action segments featuring everyday children, and episodes set in a diverse inner-city neighborhood inhabited by humans and lovable Muppet characters. The combination of educational content with appealing music, animation, puppets, and celebrity guests made *Sesame Street* a hit with parents and children alike. Today, *Sesame Street* is viewed by almost half of all preschoolers in the United States on

a weekly basis, and it has a nearly 100% penetration of its target audience of preschool-age children. It is broadcast in more than 40 other countries and has at least 10 foreign language versions.

NETWORK PROGRAMMING

In the early 1970s, child advocacy groups petitioned the Federal Communications Commission (FCC) to require an hour of educational programming for children each day from each broadcast licensee. The FCC declined to make any formal requirements, but it did develop vague standards that called for stations to try to provide a "reasonable amount" of educational children's programming. The networks responded by introducing more educational shows in 1971. NBC reintroduced *Mr. Wizard* and developed a social issues show for teens called *Take a Giant Step*; Walter Cronkite anchored *You Are There* to teach kids history on CBS; and ABC created *Curiosity Shop*, which provided answers to young children's questions about the world. However, all of these shows were cancelled after only one season, unable to compete with cartoons for ratings.

A few other shows with educational content had greater staying power on commercial television in the 1970s and early 1980s. *Fat Albert and the Cosby Kids* (1972–1984) was an animated, syndicated show based loosely on the childhood friends of comedian and educator Bill Cosby (who hosted and co-produced the show). Developed with help from UCLA educators, it presented a positive depiction of urban black youth who solved personal problems together, interspersed with humor and musical numbers. Occasionally, the networks offered specials that had educational themes. *ABC Afterschool Specials* and *CBS Afternoon Playhouse* presented dramas that dealt with social problems common to many young people, and *CBS Library* and *CBS Storybreak* presented dramatic retellings of children's literature.

The networks also introduced educational "pop-ups" shown in the few minutes between Saturday-morning cartoon programs. CBS created *In the News,* mini-newscasts for kids; ABC had *Schoolhouse Rock*, which taught grammar, history, science, and math concepts using catchy jingles and animation; and NBC aired *One to Grow On* with celebrities talking to young viewers about issues such as peer pressure and lying.

Meanwhile, PBS added to its lineup of educational programming with shows like *The Electric Company* (1971–1981), a hip program that promoted reading skills; *Zoom* (1972–1980), a show hosted by kids that encouraged young viewers to invent their own activities, games, and songs; and *Reading Rainbow* (1983–2004), a show that encouraged reading through animated versions of picture books, on-location adventures, and book reviews by real children.

IMPACT OF DEREGULATION AND REGULATION

The 1980s witnessed a huge boom in children's programming, driven by lucrative licensing of television characters. Television stations often received financial incentives to air shows based on licensed characters, so there was little motivation to air educational programming. At the same time, the government's deregulatory environment favored "marketplace" competition, and the FCC allowed broadcasters to provide whatever level of educational programming they deemed adequate. As a result, children's educational programs largely disappeared from commercial broadcast lineups.

In 1990, Congress enacted the Children's Television Act (CTA), which required television stations to air educational programming for children as a condition of license renewal. However, the bill did not specify what qualified as educational programming or how much programming was required, and it received little enforcement. In their license renewal applications, many stations claimed that popular commercial programming such as *The Jetsons*, *The Flintstones,* and *G. I. Joe* was educational. Under a new chairman in 1996, the FCC finally adopted rules that defined educational programs as those that are made specifically for children and have education as a significant purpose. The FCC also adopted a guideline specifying that stations offer 3 hours of children's educational programming a week.

RECENT PROGRAMMING TRENDS

Following the CTA, the amount of educational programming increased on network television, with shows like *Science Court* on ABC and *The Magic Schoolbus* on Fox. PBS continued to air new educational series, including science-oriented shows such as *Bill Nye the Science Guy* and *Kratts' Creatures;* the language skills show *Ghostwriter*; and the geography quiz show *Where in the World Is Carmen San Diego?* In addition, several cable channels have also offered educational

programming. The children's channel Nickelodeon added significantly to its educational offerings when it developed the Nick Jr. block of programming aimed at 2-to-5-year-olds. Programs on Nick Jr., such as *Blue's Clues, Gullah Gullah Island,* and *Dora the Explorer* were designed to encourage prosocial development and cognitive problem-solving skills. Other cable channels vying for preschoolers and their parents include Noggin (a noncommercial educational channel developed by Nickelodeon and CTW) and the *Ready, Set, Learn* block on the Discovery Kids channel. In 2005, PBS debuted Sprout, a cable channel devoted to educational programs for kids that includes advertising.

The emphasis in educational programming has shifted from cognitive skills to teaching values such as care and respect for others and to developing social and emotional competence. This trend toward prosocial education can be seen in shows like *Barney and Friends, Arthur*, *Teletubbies, Doug,* and *Recess.* The rise in prosocial programming may be attributed in part to the public's concerns about television's influence on morals and values; moreover, prosocial themes lend themselves well to the human-interest comedy format that commercial television prefers.

ELECTRONIC GAMES, ADDICTION TO

A growing number of reports in the popular press have examined excessive use of video games among children and adolescents ("joystick junkies"). Video games rely on multiple reinforcements in that different features may be differently rewarding to different people. These rewards can be intrinsic (e.g., improving a high score, beating a friend's high score, getting one's name in the "Hall of Fame," mastering the machine) or extrinsic (e.g., peer admiration). To date, there has been very little research directly investigating electronic game (video game) addiction, although almost all studies have concentrated on adolescent use. For instance, Mark Griffiths and Nigil Hunt surveyed 400 adolescents (12 to 16 years of age) to establish their level of dependence on a scale adapted from the DSM criteria for pathological gambling. Scores indicated that one in five children were dependent on computer games. Furthermore, 7% of the sample claimed they played more than 30 hours a week. Similar findings have also been reported in other studies. There is no doubt that, for a minority of children and adolescents, video games can take up considerable time, although there is still much debate as to whether very excessive video game play is a true addiction.

There have been many reports of behavioral signs of video game dependency among adolescents, including stealing money to play arcade games or to buy new game cartridges, skipping school and sacrificing social activities to play video games, not doing homework, getting bad marks at school, becoming irritable or annoyed if unable to play, and playing longer than intended. Other, indirect evidence of addictive and excessive play comes from the many health consequences that have been reported in the literature. These have included photosensitive epilepsy, auditory hallucinations, enuresis, encoprisis, wrist pain, neck pain, elbow pain, tenosynovitis (also called "nintendinitis"), hand-arm vibration syndrome, repetitive strain injuries, and obesity.

Other speculative negative aspects of video game playing that have been reported include the belief that video game play is socially isolating and prevents children from developing social skills. However, studies by Carol Phillips and colleagues and by others have found no difference in social interactions

between players and nonplayers. Adverse effects are likely to be relatively minor and temporary, resolving spontaneously with decreased frequency of play, or likely to affect only a small subgroup of children and adolescents. Excessive players run the highest risk of developing health problems, although more research appears to be much needed.

ELECTRONIC GAMES, AGE AND

As electronic games have spread to a variety of platforms, they have been used more and more by people of all ages—from very young children to adults. Because the electronic game market continues to change, use of the games is also in flux. Cultural differences among countries and among families lead to a variety of uses, and the market for games varies among countries. Nonetheless, some general trends in the United States and Europe can be described, especially in terms of gender preferences and age of users.

ELECTRONIC GAMES: ACCESS AND OWNERSHIP

Electronic games have become an important part of the children's media menu. Three quarters of all children live in households with computers, and about half of all children have access to game consoles. The rate of children's ownership of electronic games climbs sharply beginning at age 7, reaches its high point between the ages of 12 and 13, and then begins to decline. This trend can be explained by children's increased independence and reading ability as they enter school; then, during adolescence, as other private interests and school demands come into the foreground, interest in electronic games wanes.

USE OF DIFFERENT PLATFORMS

Children discover computer games very early. At age 3, one fourth of children have already played a computer game. By age 6, this number increases to two thirds. Children up to age 6 play video games, whether on consoles or on handheld devices, somewhat less than computer games. But between the ages of 3 and 6, video game use increases rapidly; by the time they enter school, half of all children have played a video game.

Like ownership of electronic games, the use of electronic games is greatest at age 13, and then gaming time begins to decrease. While about three fourths of 9-to-10-year-olds play electronic games, almost 80% of 12-to-13-year-olds do so. After age 15, the rate is lower than that for 9-to-10-year-olds. During the peak ages for playing electronic games—between 12 and 13 years—young people play such games for more than 30 minutes a day, and boys play three times as long as girls.

The use of online games first becomes significant as children reach school age and grows considerably as they become adults. The obvious reason is that parents control the purchase of telecommunications in their household and regulate their children's use of the Internet. Between the ages of 15 and 16, the number of children with their own Internet connections increases considerably.

GENDER AND GAME USAGE

Gender is an important factor in electronic game usage for children as young as 4 to 6 years. One third of girls in this age group have played a video game, and one half of boys of this age have done so. On a typical day, the difference in usage rates between girls and boys from 4 to 6 years old is enormous—not even 1 in 10 girls plays video games on a typical day, but

one fourth of all boys do. This trend holds for all age groups; for children between the ages of 9 and 16, 80% of boys play electronic games, but barely two thirds of girls do. In addition, boys spend about three times as much time as girls playing electronic games.

MEDIA FUNCTION AND GENRES

Electronic games have become a fairly important part of children's lives. In the 9-to-16 age group, electronic media are second only to TV in children's search for excitement. At the younger end of this age group, children tend to play console and personal computer games. As children get older, they increasingly prefer online games. Boys turn to e-games for excitement about three times as often as girls do.

In terms of game types, children and young people from 9 to 16 years old prefer adventure, fighting, and sport games; games with car or aircraft themes; and card games, board games, and puzzle games. Within this group of themes, there are clear differences in preferences according to age and gender. The differing interests of adolescent boys and girls are reflected in each group's predilection for certain e-games.

Boys' interest in various genres of electronic games is generally constant across age groups. Boys prefer fast-action games. Boys 6 to 16 years play mostly fighting games, sports games, and car games. Additionally, from about age 11, boys develop an enduring interest in games in which they must plan things.

Girls, on the other hand, tend to prefer narrative games. Adventure games also seem to interest girls of all age groups. Other genres preferred by girls are somewhat more varied: Whereas younger girls are more interested in drawing, painting, and teaching games, girls age 15 and older are more likely to play card games, board games, and puzzle games.

GENDER AND GAME AVAILABILITY

The fact that boys play more e-games than girls do is clearly related to the kinds of games available; electronic games are made mainly for boys. Boys are interested in sports, adventure, and science fiction, and they play games that correspond to these interests. Girls, on the other hand, have different preferences, and their interests change during adolescence more than those of boys. Because girls find fewer games that suit them, they turn to other media that better fit their needs. The huge success of the computer game *Sims*—in both younger and older age groups—shows that girls, too, will embrace a computer game as long as it matches their interests.

ELECTRONIC GAMES, COGNITIVE EFFECTS OF

The cognitive effects of playing electronic games relate to information processing, gaining understanding, and acquiring knowledge. Thus far, research generally has focused on basic aspects of information processing. The established effects on the gamer's cognitive system are diverse and almost always positive. Cognitive effects found among groups of children and college students have included, for example, more focused visual attention, better spatial representation, and enhanced memory. Research on positive effects somewhat counterbalances the emphasis on negative effects. The recognition of the positive cognitive effects of gaming points to a vast educational potential inside, and particularly outside, the classroom.

The possible cognitive effects are very much dependent on the kind of electronic game that is played. Simple Internet games that can be completed in less than a minute may affect the basic modalities of information processing, in particular with respect to the visual and attentional systems. Today's complex 3-D games that require dozens of hours to reach the final goal may also influence more advanced cognitive skills, such as deductive reasoning, planning strategies, and decision making.

Research on the cognitive effects of electronic games has been dedicated largely to basic kinds of cognitive processing. Pioneering work was done in the early 1980s by Geoffrey Loftus and Elisabeth Loftus. In *Mind at Play*, they discussed the possible effects of the arcade games of that time on, for example, memory, attention, and eye-hand coordination. Research about cognitive effects was advanced in the 1990s by Patricia Greenfield and her colleagues. In their series of studies, the Greenfield team found effects of gaming on different aspects of the cognitive system.

A first effect was found with respect to *spatial representation.* This is a basic cognitive skill involved in dealing with two-dimensional images of a hypothetical two- or three-dimensional world. Greenfield and her team studied spatial representation in the context of a rather basic arcade game. Their 10- and 11-year-old participants were invited to play *Marble Madness*. The game involved guiding a marble along a three-dimensional grid. The results showed that spatial performance improved as a result of playing the game. The effect did not occur when children practiced on an electronic word game.

A second effect concerned *iconic representation,* the ability to read images. For most people, this ability is less well developed than verbal kinds of representation. The Greenfield team found that playing an electronic game shifted representational styles from verbal to iconic. Undergraduates from the United States and Italy played *Concentration* either on a computer or on a board. In the subsequent test, the participants were asked to describe a computer animation they had seen earlier. The computer gamers used more diagrams, an iconic kind of representation, whereas the board gamers used verbal descriptions.

A third effect occurred with respect to *divided visual attention*. Playing an electronic game requires that players keep track simultaneously of many stimuli at different locations in the visual field. This can be done only if players are able to quickly shift their attention from one set of information to another. One of the Greenfield studies confirmed that expert players of electronic games are better at dividing their visual attention than novices. The participants had to locate a target on the computer screen as rapidly as they could. When the target appeared in an unexpected location, expert players responded faster than novices. More recently, Shawn Green and Daphne Bavelier tested visual attention and its spatial distribution in an experiment. One group with no earlier experience with electronic games was asked to play *Medal of Honor,* a rather complex 3-D war game that requires divided visual attention. The participants were trained for 1 hour per day for 10 consecutive days. A second group, the control group, played the puzzle game *Tetris.* It is less complex and does not appeal to divided visual attention, because it demands focus on one object at a time. After 10 days, only the *Medal of Honor* gamers showed a significant increase in their capacity for divided visual attention.

A fourth effect concerned the *visual-spatial link.* Greenfield and her colleagues investigated a possible link between the visual system and the spatial representation of objects. The college students in their study first played *The Empire Strikes Back.* The game required navigating through 3-D space represented on the two-dimensional computer screen. To test the cognitive effects, participants were then asked to perform a mental paper-folding task. They had to imagine how they would fold a piece of paper. A comparison between expert players and novices showed that the experts were better at the task. The practice of gaming made it easier for them to imagine the spatial representation of an object, in this case a piece of paper.

With regard to the cognitive function of *memory,* Loftus and Loftus pointed out that the rapid attention shifts that are part and parcel of electronic games require the immediate storage of new information. One must, after all, remember the position of the original visual stimulus when confronted with a novel one. More recently, Anne-Siri Oyen and James Bebko studied the effects of gaming on memory from a different angle. They investigated whether gaming would enhance memory for content. They found a positive effect: Children from 4 to 7 years old were better at remembering pictures from an interesting electronic game than pictures presented in a formal lesson.

Research on cognitive effects of electronic gaming has been of limited scope. Nevertheless, it points to the educational potential of these media. Electronic games are played for fun, but the entertainment experience goes hand in hand with the enhancement of

important cognitive functions. If players and their parents succeed in preventing excessive play, gaming may turn out to be a beneficial experience for many.

ELECTRONIC GAMES, COGNITIVE SCRIPTS AND

Electronic games (video games, including console, handheld, and computer-based games) have become a common leisure choice for children and adolescents. However, many of the most popular games have considerable violent content. To be a successful player, a cycle must be established in which one chooses preprogrammed violent actions and is reinforced for one's choices. There is concern that this repetition and reinforcement could lead to the development of cognitive scripts for aggression and violence that are outside of player awareness and that could later affect situation perception and behavioral choice.

THE DEVELOPMENT OF COGNITIVE SCRIPTS

To understand the concept of cognitive scripts, the concept of knowledge structures must first be defined. Memories of past experiences are stored as knowledge structures, and these structures determine, in part, how people understand and respond to new experiences. A cognitive script is a specific type of knowledge structure, a general representation of how common events typically unfold. It is literally a "script" for behavior, much like a screenplay, which dictates the actions of the actors. Scripts tell us what to expect and what to do in common, frequently encountered situations. Cognitive scripts begin to develop early in childhood, typically between ages 2 and 3, based on children's daily life experiences and their observations. For children, scripts may be developed for such activities as how to behave at a birthday party or in a fast-food restaurant, or how to respond to perceived provocation. Script development continues throughout life. For example, adolescents and adults develop scripts for such common activities as driving a car.

THE ACTIVATION OF COGNITIVE SCRIPTS

Once a coherent representation is developed, cognitive scripts are stored as knowledge structures in long-term memory. Cognitive scripts then may be activated automatically, without conscious awareness, given the appropriate experiential triggers. A script is activated when related memories are energized through exposure to a new situation that is similar in some way to the existing cognitive script. When a new experience triggers a preexisting script, the individual will either act in accordance with the script or will fantasize about the actions. Acting on or fantasizing about the script (*cognitive rehearsal*) may ultimately increase the script's accessibility as new associations with similar concepts are built and existing associations are strengthened. Memories and experiences with similar meanings and those that are often activated together develop the strongest associations. Therefore, scripts not only function independently but also may cluster and form a network of behavioral choices. Because a large number of situations can activate this network, particular types of scripts may become chronically accessible, may be more easily triggered, and may be resistant to change. Scripts for aggression are thought to be particularly resistant to change.

COGNITIVE SCRIPTS AND VIOLENT VIDEO GAMES

In any situation, a number of competing scripts could be triggered and enacted. In addition to relevance to the situation, scripts must be consistent with perceived

social norms. Certain social norms, including those regarding the use of aggression and violence, dictate that ethical beliefs guide behavioral choice and thus trigger a process of moral evaluation. Once this process is initiated, higher-order emotions (such as empathy) and knowledge structures (such as attitudes relevant to the situation) are activated. However, desensitization to the ethical implications of aggression and violence could interfere with moral evaluation processes. Violent video games present aggression and violence as justified, without negative consequences, and fun. Repeated exposure to these messages, and practice and reinforcement of violent actions in the game context, may desensitize players to the true impact of violence. It is reported that the army has used video games to desensitize soldiers, and emerging research suggests that children and adolescents with a preference for violent games have lower empathy and stronger proviolence attitudes, suggesting possible desensitization.

The cycle of demonstration, practice, and reinforcement makes the video game-playing environment ideal for the development of cognitive scripts related to game activity. In the case of violent video games, chronically accessible scripts for aggression may be established. Individuals will then tend to focus on information that is consistent with the script and overlook or distort inconsistent information. Children and adolescents with chronically accessible aggressive scripts may process neutral situations as though they are aggression related. For example, a child who is repeatedly exposed to violent video games in which hypervigilance against threat and aggressive responses are valued and rewarded may misperceive an innocent nudge in a crowded lunch line as an act of aggression and retaliate with an angry push back.

Given the popularity of violent video games, their potential for encouraging the development of aggressive scripts, and the possiiblity that desensitization to violence will subvert the moral evaluation processes that inhibit aggression, policymakers need to evaluate all options to protect children from unintended adverse effects of exposure to violent video games.

ELECTRONIC GAMES, EFFECTS OF

There is a great deal of controversy over what the effects of electronic games may be on young people. Public and media attention have tended to focus on the perceived harms of electronic game use—particularly claims that playing violent games may encourage violent behavior—and much experimental research has been done to attempt to establish such a link. Excessive game play has also been linked with physical and psychological harms. However, a significant number of academics see computer games as potentially or actually beneficial to players—improving problem-solving skills, for example—and these researchers tend to suggest that studies showing harmful effects are flawed.

The claims of both sides can be divided broadly into two categories: (a) those that deal with effects thought to stem from the kind of content found in games (e.g., violent imagery on the one hand, educational content on the other) and (b) those that involve

effects thought to relate to the nature of electronic games themselves (e.g., their "addictive" nature, on the one hand, and their exercise of eye-hand coordination skills, on the other).

Any assessment of the overall impact of electronic games on young people is and seems likely to remain very difficult, both because researchers have tended to concentrate on the particular aspects of most interest to them, ignoring other aspects, and because the content and even the fundamental nature of computer gaming continues to change as technology advances.

CONTENT EFFECTS

Violence

The most studied area in electronic games research, particularly in research about young people, is undoubtedly the theorized link between violent game playing and violent behavior. The leading theoretical model for this link is Craig A. Anderson's general affective aggression model, which suggests that playing a violent game can cause violent thoughts, feelings, and even physical symptoms (elevated heart rate) that, if repeated over time, can change habits of behavior, leading to more aggression. Steven Kirsh suggests in a research review that younger adolescents may be particularly at risk for influence by such games, both for developmental reasons and because game playing tends to be at its highest at this stage of life.

For ethical reasons, direct experiments on children have not been done; however, experiments have been conducted with college students, and survey-based studies have been done with younger children.

Surveys of both children and adults have shown a link between playing violent electronic games and violent attitudes and behavior, but it is not clear whether the games lead to violence or whether violent children tend to prefer violent games (or both). Studies tracking gamers over a period of years would be necessary to determine which of these two factors is more important and to help to understand whether any effects are short-term or long-term, but such studies have not yet been done.

When lab experiments have been done (often with college students), they have tended to show at least a short-term increase in aggressive thoughts and actions. In an influential study by Craig A. Anderson and Karen E. Dill, undergraduates played a violent electronic game (*Wolfenstein 3D*) for three 15-minute sessions. When tested immediately after each session, they responded to a blast of noise with a longer blast of noise than students who had just played a nonviolent game. The violent gamers also read words associated with aggression in a subsequent test more rapidly than the control group, which the researchers suggest indicates higher "accessibility of aggressive thoughts."

Meta-analyses of the experimental literature (studies that attempt to combine the results of several articles on similar themes) have suggested that, where playing violent electronic games is linked to violent behavior or attitudes, it explains about 4% of such behavior.

Because of the (necessarily) artificial nature of experimental aggression testing, however, these findings and others of a similar nature have been questioned by more skeptical scholars. It is widely accepted that, if there is a connection between violent electronic game use and violence, it is only one of several influencing factors. More research has been called for to explore in detail what particular kinds of violence in games might be most harmful, what the long-term effects might be, and what kinds of backgrounds are most likely to make children (or adults) vulnerable to "picking up" violent behavior from violent games.

Whether or not violent gaming is shown to lead to violence, however, many scholars argue that the precautionary principle should prevail, and children should be protected from violent content because it may well be harmful, and there is no evidence that violence in games is in itself beneficial.

Stereotyping and Other Undesirable Content

Gender

Although game violence has received the most attention, other forms of potentially harmful game content have also been studied. One study examined the most popular games available on several game consoles and on PCs and found that only 16% of human characters in the games were female and that sex roles were frequently stereotyped. A similar study 4 years later found, in addition, that a quarter of women shown in electronic games had unrealistic body types (compared with 2% of men) and that 41% of women in games wore sexually revealing clothing. This, they argue, could contribute to low self-esteem among women who see or play these games.

Race and Propaganda

David Leonard examined *Grand Theft Auto III* and various American sports games and found that they tend to reinforce racial stereotypes. In addition to inadvertent bias in games, a number of groups are attempting directly to harness games to influence those who play them. "Propaganda" games range from those used as a recruitment tool by the U.S. Army, which has a multimillion-dollar budget, to smaller-scale projects such as *Under Ash/Under Siege,* which portrays Palestinians fighting a brutal Israeli occupier, and *Ethnic Cleansing,* produced by the openly racist National Alliance, which encourages the player to kill African Americans, Jews, and Latina/os. By contrast, the United Nations' *Food Force* game teaches some of the challenges faced in the delivery of food aid.

There are also a number of games with religious messages, and companies are increasingly embedding advertising and product placement in games (analysts predict spending for this could rise to nearly $1 billion by 2010). In-game advertising has been little studied outside of marketing journals, so its effects are not clear yet, nor is whether the effects are any different from those ascribed to advertising on television and in other media.

Educational Content

There is a thriving market in explicitly educational game software (*edutainment*), which attempts to teach children a broad range of content and skills, from simple rote learning games to business and other simulations designed to help them understand complex processes. In addition, many popular games have educational components. *Civilization* and *Age of Empires* games, for example, provide information about various early civilizations in the interactive help file and manual for the game, although they may be inaccurate or harbor ideological biases. Some educators believe that many electronic games can help children learn even when their content is not explicitly educational.

MEDIUM EFFECTS

A number of scholars claim that effects can be ascribed to computer game playing regardless of the nature of the game itself. Arguably, however, given the immense diversity of game genres—from *Solitaire* on Windows to massively multi-player fantasy worlds such as *Everquest*—most theories of game medium effects make some assumptions (tacit or explicit) about the genre (and content) of the games they are studying. It is also reasonable to suppose that any effects of game playing would be different in different cultures that have different attitudes toward computers and games, but, unfortunately, there have been few cross-cultural game studies.

Addiction

It is clear from surveys that, although the majority of game players play "normally," a small number play the game or games of their choice more than might be considered socially acceptable. For example, almost 1 in 10 adolescents from a self-selected sample of *Everquest* players told researchers they played the game for more than 50 hours a week. Even those who played less often reported significant displacement of other activities; more than a fifth of all the adolescents in the sample reported sacrificing work or study to play the game, and a similar proportion reported sacrificing sleep.

Two large-scale surveys of adolescents 12 to 16 in the UK found that 7% played computer games for 30 hours or more per week. It is still not clear what level of game play should be considered "addiction," what might cause game addiction, which children might be vulnerable, or whether, in the absence of games, the same children might have become "addicted" instead to other activities such as watching television or reading books.

Obesity

A number of researchers (and press commentators) have tried to draw a connection between excessive electronic game use and obesity among children and adolescents, just as earlier studies have attempted (largely unsuccessfully) to link obesity with television watching. A large-scale study in the United States (from data collected in 1997) found that lower-weight children played electronic games either very little or a lot, and that girls with higher weight played more games, but boys did not—results that are difficult to interpret.

Other Forms of Physical Harm

A variety of health risks have been associated with electronic game play. Epileptic seizures can be triggered by flashing lights, which are present in some games, and musculoskeletal problems (e.g., wrist injuries) can be caused by awkward or sustained

postures and repetitious movements during excessive play. A recent review of research found that, although no studies have yet been conducted to establish the prevalence of physical harm to children and adolescents from excessive game play, case studies and lab reports provide persuasive evidence that concern is warranted. However, there is little evidence of serious adverse effects from normal play, and effects normally disappear when gaming is reduced.

Loneliness

It has been suggested that excessive computer game use might harm children's social development by taking away from the time they have available to socialize face to face. Surveys of young people overall have found either (a) that no social differences exist between gamers and nongamers, or (b) that frequent gamers actually meet friends outside school more often than less frequent players do. However, a survey of 1,000 Flemish children 8 to 10 years old found that the 10% of children who played games heavily—more than 2 hours a day—tended to be more socially isolated than those who played less. Whether heavy gaming causes isolation or is an attempt to compensate for it is not clear. Studies have tended to be of single-player gaming; the social effects of online play with multiple players may be different.

Physical Benefits

Although electronic games are often associated with health problems, they can also be used to improve the health of the unwell. For example, games have been shown to be effective in distracting patients from pain and have been used as a form of physiotherapy and even as a means to help retarded and autistic children learn to interact, although these effects have not been studied over a long period. There is also some evidence that electronic game play can improve eye-hand coordination and spatial intelligence (pattern matching and the like). Some academics have suggested that a significant rise in scores on the nonverbal part of IQ tests in the last few decades can be attributed to the increased amount of electronic game play.

Higher-Order Cognitive Benefits

A number of scholars and commentators have suggested that games can teach children valuable mental skills. In his book *What Video Games Have to Teach Us,* James Paul Gee outlines 36 ways children—and adults—can be educated by "good" games (a class of games that, in his view, is not restricted to explicitly educational games but can include "first-person shooters," such as *Half Life*). These positive outcomes include (a) learning how complicated sign systems operate through understanding the way a game operates, (b) having the opportunity to play with virtual identities and reflect on one's own, and (c) exercising knowledge gathering through social networks when gamers swap tips on how to complete a game. Whether the skills learned through gaming are transferable to other situations, and in what circumstances they are transferred, remains to be shown.

ELECTRONIC GAMES, GENDER AND

Early studies of computer and electronic game use among children and adolescents consistently revealed

that girls were less likely than boys to spend time on these activities. With the introduction of the Internet, however, many of these gender differences in use have dissipated. For example, recent studies indicate that girls are just as likely as boys to use the Internet. Gender differences still are found, however, in the area of electronic gaming (i.e., computer, video, arcade games). More boys than girls report gaming, and boys report playing games different in type from those reported by girls. Concerns have been raised about this gender “imbalance” in game playing. At issue is the fact that moderate levels of electronic game playing may be positively related to computer literacy and cognitive development (e.g., spatial skills, decision making, reaction time, etc.). Girls who are nonusers, therefore, may be missing out on an important learning tool.

FREQUENCY AND TYPE OF ELECTRONIC GAME PLAYING

A consistent finding in the literature is that boys report playing electronic games more than girls do. Girls tend to be overrepresented among the nonusers. In addition, boys are much more likely than girls to be heavy game players (e.g., more than 30 hours a week), although this subgroup of males typically is small. Clear gender differences also are found in the type of electronic games that are played. Boys are more likely than girls to play sports, action, fighting, strategy, role-playing, and racing games. Heavy game players also are more likely to report playing violent games (e.g., fighting, action). Although girls also play violent games, they are more likely than boys to play educational games, puzzles, quiz and board games, and art games and to list them as their favorite games. Interestingly, girls and boys both are equally likely to report playing games that involve building model worlds. For example, girls appear to enjoy playing games such as *SimCity* and *The Sims* more than the more violent games that are popular with boys.

EXPLANATIONS FOR GENDER DIFFERENCES

It is difficult to know the cause of these gender differences, but multiple hypotheses have been generated. For example, games are created for the most part by males for males. The content of the games (competition, speed, violence), therefore, may be more attractive to boys than girls. Critics argue that many games have stereotyped and weak female protagonists or no female characters at all. Others have argued that the male bias in game design has resulted in more games with features that might match boys’ cognitive strengths. For example, some researchers argue that males, on average, tend to be better than females at skills such as spatial rotation and targeting (the ability to calculate trajectories of moving objects). These skills are rewarded in many electronic games. On the other hand, females, on average, may be stronger in object location, verbal memory, and color memory. Girls may prefer puzzles, card games, and board games because these games tend to draw on those skills. This is not to suggest, however, that girls lack the skills to play many electronic games; but at the beginning they may be at a disadvantage compared with boys. Importantly, this hypothesis does not appear to account well for the many games that require multiple skills.

Furthermore, researchers have suggested that gender differences in electronic gaming may exist because educational institutions often promote computer use among boys more than among girls. Girls also may have less social approval from peers for engaging in more-than-moderate levels of electronic game use. Other researchers have suggested that electronic games may not provide the social interaction that girls seek. Indeed, girls’ computer activities appear to be weighted more toward communication activities, such as email and chat rooms. Developers of electronic games have attempted to address some of these concerns by creating software geared specifically to girls, often by including nonviolent themes and female protagonists. These attempts, however, have not always been successful.

Clearly, there are multiple potential explanations for why boys consistently report playing electronic games more than girls, and research evidence to support these hypotheses is limited. For example, what might be *causes* and what might be *effects* of these differences in game playing still is unknown. In addition, it may be that girls are not necessarily disadvantaged because they play electronic games on average less than boys do. The link between electronic game use and positive youth development is not clear. Most importantly, these gender differences obscure the fact that within-group differences also are significant. In other words, there are many girls who play electronic games and boys who do not play electronic games.

It is only on average, or across the groups of boys and girls, that we find gender differences in electronic game play.

ELECTRONIC GAMES, HIGH-RISK PLAYERS OF

There has been considerable debate in recent years about the risks associated with violent electronic game play by children and adolescents, with some arguing for powerful effects and others suggesting the effects are trivial. However, many of these debates overlook one important consideration: Not all players are affected equally. As Michael Slater and colleagues argue in their downward spiral model of media effects, some youth may be relatively unscathed by media violence exposure, whereas others may be especially vulnerable to its influence. In other words, there may be what Jeanne Funk has called *high-risk players* of electronic games.

Many risk factors for youth violence have been identified; this entry focuses mainly on risk factors identified in scholarship on electronic games. The surgeon general's report on youth violence contains a more comprehensive set of risk factors. With respect to electronic games, it is important to remember that individual risk factors are not causes of gaming effects. Instead, they should be viewed as a set of conditions that facilitate the prediction of gaming effects, especially when several are present at once. A growing body of literature suggests how developmental, personality, social, and emotional factors, along with exposure to certain game content and technology, may put particular children at higher risk for negative game play outcomes such as aggressive behavior.

AGE AND DEVELOPMENTAL DIFFERENCES

Age and cognitive development of children may put them at greater risk for harm from electronic game play, with younger children being most susceptible. Because these children tend to focus on perceptually salient attributes of media such as video games, their attention may center on flashy violent content and exclude other contextual features, making them more susceptible than older children to the influence of violent content. Furthermore, Jeanne Funk suggests that children are at higher risk than adolescents because they lack the ability to measure their behavior in light of moral standards and the behavior of others. Without these influences, children are less likely to feel guilty about aggressive behavior and may internalize the violent worlds of popular video games as models for acceptable behavior. Although most evidence points to children being at higher risk, certain adolescents may also be at high risk because of their greater willingness and ability to engage in reckless behavior and because they may develop stronger, more complete scripts for violent behavior as a function of repeated electronic game play over time.

TRAIT AND PERSONALITY PREDISPOSITIONS

As suggested in the general aggression model (GAM) developed by Craig Anderson and colleagues, certain trait or personality attributes may make electronic game players more at risk for aggressive behavior. In one study, Anderson and Karen Dill surveyed

227 students and found real-life game play to be associated positively with aggressive behavior and delinquency, especially among males and individuals with greater trait aggression. Indicators of aggressive personality, which may include aggression and irritability, have been shown to relate positively to aggressive outcomes in both survey and laboratory studies of media violence effects. Children and adolescents with some form of aggressive personality are especially likely to be high-risk players of electronic games.

Several other personality factors may impact risk levels. Sensation seeking has been shown to create more robust positive relationships between violent media exposure (including video games) and aggression among teens. Type A personalities have been found to experience a greater level of arousal while playing electronic games than Type B personalities, increasing the risk of addiction for Type A personalities. Addiction or dependency on electronic games may result in more frequent rehearsal of violent in-game behaviors, thereby strengthening cognitive scripts for aggression as suggested by the GAM. There are other personality factors that may put players at higher risk as well, especially when several are present at once.

SOCIAL AND EMOTIONAL FACTORS

Social problem-solving deficiencies are one reason both bullies and victims tend to be higher-risk game players. Bullies also display acceptance of intimidation of others, a general lack of empathy for victims in games, and low levels of remorse for violent behaviors. Victims tend to be highly emotionally reactive to the intimidation of bullies and may seek violent video games as a means of acting out their opposition to bullies without fear of reprisal. Although electronic games do not create bullies and victims, they may emphasize extant behavior patterns. Indeed, Michael Slater and colleagues found that victimization and sensation seeking moderate the relationship between use of violent media and aggressive behaviors, such that violent content reinforces experiences of anger.

Lack of parental influence may also place children at higher risk for gaming effects. Poor bonding with parents and peers has been associated with increased levels of emotional distress and instability. Children and adolescents with impaired emotional regulation skills may not experience, or may seek to maintain, a certain degree of negative arousal. When electronic games are used as a source of this arousal, children are at higher risk for addiction to or dependence on electronic games. When games are taken away, addicted or dependent children may experience symptoms of withdrawal. The positive effects of parental influence, however, may diminish when children reach adolescence and attempt to assert their independence from their parents.

THE ROLES OF USE, CONTENT, AND TECHNOLOGY

Children and adolescents who regularly play electronic games for extended periods of time are at higher risk for several reasons. In addition to strengthening aggressive personality, consistent with the GAM, excessive play may also be symptomatic of addiction or dependency. Most games have an addictive reward structure, making it easy for a child to lose track of time and get caught up in the experiences of a game to the exclusion of all else (called a *flow* or *presence* state). As Jeanne Funk documents, playing frequently can have negative effects because it displaces other, developmentally appropriate pursuits. She also notes that a strong preference for violent electronic games further adds to the high-risk status of players.

Indeed, certain types of game content and technology should put players at greater risk. Over time, games have evolved into increasingly realistic experiences, and young people who play newer violent electronic games, such as those taking place from a first-person perspective, may be more likely to identify with aggressive game characters than those who play older games with less salient models. Given the continual push by the gaming industry to provide players with more realistic experiences, the next generation of electronic games may have more potential to harm. A few studies have examined the role of virtual reality (VR) technology on game-induced aggression; VR technology strengthened aggressive outcomes among certain players compared to standard game technology. As games incorporate more realistic graphics and interfaces, such as ones allowing for real punching and kicking instead of just button pushing, they may place those players at higher risk due to the repeated rehearsal of actual violent behaviors.

ELECTRONIC GAMES, HISTORY OF

The roots of modern electronic games can be traced to coin-operated electromechanical games, such as *Championship Fast Draw* from 1964. Elements like the high score and one- and two-player options were part of this early game. The first electronic game is possibly an interactive game similar to table tennis that was developed by William Higinbotham in 1958. It was played on an oscilloscope at Brookhaven Laboratory in Upton, New York. The gaming industry expanded greatly during the 1970s and 1980s, especially after the advent of the data cartridge and handheld games. Online gaming became increasingly popular in the 1990s. Today, the main driver of the development of electronic games is the growing power of the hardware, which makes games more and more realistic and complex.

MANY FATHERS

The first interactive computer game, *Space War,* was developed by Steve Russell, a student at the Massachusetts Institute of Technology, in 1961. Russell never filed for a copyright or a patent for his game. The next important step in the development of electronic entertainment was made by Ralph Baer. He worked for Sanders Association in New York, a military contractor. Between 1967 and 1972, Baer developed the first gaming machine, Odyssey, which was brought out by Magnavox. Odyssey had several games, including one that simulated ping-pong. Russell and Baer are known as the forgotten fathers of the electronic gaming business because their innovations brought them no economic success. At the time, computers were too expensive to be used as a gaming platform for *Space War,* and Magnavox did not have the marketing power to make Odyssey popular.

The first well-known figure in the electronic gaming business is Nolan Bushnell. His first exposure to electronic games was *Space War,* which he played in college. He developed a version of this game for coin-operated machines and gave it the name *Computer Space,* but it had no real success. He then founded Atari, which developed many legendary electronic games, such as *Pong,* the first big success on the market. Atari had to pay Magnavox for the licenses to *Pong* and *Space War.* Until 1974, *Pong* machines were in nearly every bar in the United States. A third of the machines were made by Atari and the rest by other companies through a license. In 1975, Atari released a consumer version of *Pong,* which sold 150,000 copies in the first year. This was the beginning of electronic home entertainment.

COMPETITION AND TECHNICAL DEVELOPMENT

In the following years, a number of new companies, games, and machines entered and left the market. A major innovation in these years was the data cartridge. After the advent of the cartridge, the game was no longer stored in the read-only memory of the gaming machine, which made it possible to buy new games for gaming machines. This changed the distribution structures of the industry; companies now had the ability to develop new games for the existing hardware and to work as developers and publishers of gaming software.

The next important steps in the development of the industry were, first, the start of handheld gaming in 1977, when Mattel brought LED-based games to the market, and second, Japan's entrance onto the electronic gaming scene when Nintendo released its first game in 1978. The industry grew considerably during the late 1970s and early 1980s. In the 1980s, the increasing costs of development in hardware and software ushered in a phase of consolidation. As a result, the structure of the market changed; now, there were companies specializing in software, like Midway, and others specializing in the publishing process, like Electronic Arts, founded in 1982. The third group of companies, including General Consumer Electronics, which brought out the Vectrex in 1982, specialized in the development of hardware. Only a few companies, such as Atari and Nintendo, worked in more than one market. In 1989, Nintendo released the first Game Boy, which is the most successful gaming platform to date. Nintendo also sold more than 120 million consoles. The company was clearly a leader in the video game business, both in the handheld and home console markets. Popular consoles from Nintendo were the family computer Famicom, which was released in 1984 in Japan, and its American version, the Nintendo Entertainment System (NES). Up to the mid-1990s, many companies brought out new platforms, but most of them were unsuccessful. With the growing number of PCs in households, the PC also became more and more important as a gaming platform. In 1993, Sega's Genesis System and Nintendo's Super NES dominated the console market.

Online gaming emerged during the late 1970s in Great Britain. A student, Roy Trubshaw, developed the first multi-user dungeon (MUD) at the University of Essex in 1978. In these multiplayer games, a group cooperates in the action of the game. The British students taking part in this initial network gaming played with students from the United States, using the early Internet and the ARPANET (the network developed by the Advanced Research Projects Agency of the U.S. Department of Defense). In the period between 1978 and 1985, about 100 people played in this first MUD. In the following years, many licenses of the game were sold. Between 1987 and 1999, the online service CompuServe used the license under the name British Legends. The following generation, MUD2, was developed by British Telecom. Both games are still available over the Internet. These first online games were text adventures. The next step in the development was graphics adventure. One of the first complex games was *Habitat,* developed by Lucas film in cooperation with Quantum Link. Licenses of this game were known as Worlds Away and Dreamscape. In the second half of the 1990s, popular games such as *Ultimo Online* were developed. The Internet boom caused a boom in online gaming, too, with the emergence of games involving complex worlds such as those in the Internet games *EverQuest* (Sony) or *Asheron's Call* (Microsoft)

NEW DOMINATORS OF THE MARKET

The domination of Sega and Nintendo ended in 1994 when the Sony's PlayStation came out. The first PlayStation was a huge success, surpassing both Nintendo and Sega in popularity. In the following years, Sega tried to stay in the hardware market but ultimately decided in 2001 to concentrate on software development. Dreamcast was the last console Sega released to the market. In competition with Sony, Nintendo began to specialize in children's games, whereas Sony targets older age groups. Today, the first PlayStation is still one of the pre-eminent gaming platforms. It was followed by the PlayStation 2 in 2000, which at the time was the most successful platform. In 2001, Microsoft became a competitor in the gaming scene with its console Xbox. In 2005 and 2006, the next generation of gaming machines entered the market. There is currently stiff competition, especially between Microsoft and Sony, as the two companies target their machines to the same age groups.

THE FUTURE OF GAMES

Modern game consoles are multimedia machines with enormous graphic power that can be used as multimedia devices for CDs, DVDs, the Internet, and so forth. Another area of technical development important for the games business is the increasing transmission rates of telecommunications networks. In the future, online gaming with PCs and consoles will be a very important part of the electronic game business. The number of users in the network gaming community on Microsoft's Xbox Live service measures in the millions, as does the number of players of the online game *Warcraft.*

ELECTRONIC GAMES, INTERNATIONAL

Electronic games is the umbrella term for interactive games that are played on different kinds of electronic media. It includes all digital interactive games, whatever the platform they are played on. Electronic games come in an almost endless variety. They range from trivial puzzle games on the Internet that can be completed in less than a minute to highly realistic, three-dimensional (3-D) console games involving a sequence of complex actions that take dozens of hours to complete. In the short history of electronic gaming, both the production and the reception of electronic games became an international enterprise. Games are produced for a global market of mass entertainment. All over the world, games have attracted a wide audience, in particular children and (young) adolescents.

CHARACTERISTICS OF ELECTRONIC GAMES

An electronic game is an interactive, rule-governed system based on computer processing power. Rules are a fundamental feature that electronic games share with all other games. The outcomes of the interactions are variable because they depend on players' efforts; when players do not communicate with the game, it simply stops. As in other games, players care about the outcome of the game. Serious players want to win, after all, and feel disappointed when they lose. In electronic games, the structure of credit points teaches players immediately that some outcomes are positive and some negative.

INTERNATIONAL PRODUCTION OF GAMES

Today, the development, production, and distribution of electronic games constitute a large industry involving many commercial partners. The process of game production begins in a development studio, where ideas are generated. If the studio succeeds in persuading a game publisher of the idea's value, an advance sum is allocated, and actual development begins. A design team of 30 to 40 writers, graphic designers, programmers, musicians, and quality testers works for about a year and a half on a new game. After approval of the final version, the game is mass-produced and distributed. The international market for electronic games is highly competitive. Estimates are that only about 5% of the games make a profit. However, these profits are huge in the case of blockbusters like *The Sims*, *Halo*, or *GTA: San Andreas*, but such profits are often needed to cover losses on less successful games.

Competition has led to concentration in the gaming industry on a level comparable with the movie and music industries. Many small, independent developers from the early days went out of business or were bought by other companies, as in the case of Maxis, the developer of *SimCity* and *The Sims*, which is now owned by Electronic Arts. Mergers between publishers and many takeovers further contributed to the industry's concentration. In this process, Electronic Arts became the world's largest game publisher.

The international game industry is dominated by publishers and developers from the United States, Japan, and the United Kingdom. The American companies (e.g., Electronic Arts, Atari, Id Software) have the largest global market share. Japanese companies (e.g., Konami, Square Enid, Sega) are second in the world game market, but they dominate the local Japanese market. The British game industry (e.g., Adios Interactive, Sic games, Rockstar Games) produces successfully for the world market, but its volume is far smaller than the American and Japanese output. Developers and publishers in other countries are mostly small. French Besot is the exception: It is on the edge of the world's 10 largest game publishers.

The production of game consoles is dominated by Japanese companies. Sony is the undisputed market leader, with the PlayStation (1995) and the PlayStation 2 (2000). In response, Nintendo released the Nintendo64 in 1996 and the Game Cube in 2002. Nintendo is particularly strong in the handheld market. The Game

Boy (1989) and its sequels reached a massive audience. In 2004, they launched the Nintendo DS (Double Screen). Sony joined the competition for the mobile gamers in 2004 with the PlayStation Personal (PSP). Microsoft became the American competitor in the market with the launch of the Xbox in 2001. Both Microsoft and Nintendo will continue to attack Sony's dominant position with their new consoles in 2006 (Microsoft's Xbox 360 and Nintendo's Way). But Sony promises to have a new PlayStation (PS3) on the market in 2007.

The concentration of companies in the gaming industry is further underlined by the fact that the console manufacturers are large publishers of games as well. Nintendo is by far the oldest. It started in 1889 in Kyoto, Japan, with the publication of playing cards. Almost a century later, the company turned to electronic games. Microsoft first published games for the Windows PC and now also publishes for the Xbox. The games of Sony Computer Entertainment are part of a far larger Sony conglomerate that produces content for different media, including music and films.

Contemporary electronic games generally reflect the global dominance of Anglo-American culture. They feature the English language, even when their origin is Japanese. Large titles often are adapted for local contexts, offering a choice of languages for screen display, instructions, and sometimes dialogue. Online gaming on the Internet is a truly global enterprise. The hundreds of thousands of *EverQuest* gamers, a successful massively multiplayer online role-playing game (MMORPG), reside in different countries.

Playing electronic games is embedded in a wider international game culture that manifests itself clearly on the Internet and in print media. The number of websites dedicated to gaming is uncountable. Many sites provide general news about electronic games, and the industry (e.g., www.IGN.com and www.gamespot.com). Other websites are dedicated to specific titles. They often have the character of fan sites. The postings on, for example, the sites of *Final Fantasy X-2* and *The Sims2* illustrate the international composition of the audiences of these games.

Game culture is also represented in the wide range of print media about gaming, notwithstanding the digital, electronic nature of games. The independent and critical British magazine *Edge* (1993) is one of the highbrow titles. *AmiPro* (United States, 1989) and *PC Gamer* (several local editions, 1994), aim at wider audiences. *Nintendo Power* is an example of a popular magazine published by the industry. Finally, game culture is represented by T–shirts, shoulder bags, and a variety of gadgets. This kind of merchandise often is part of cross-marketing initiatives. *Pokémon* obviously is one of the most successful titles and is distributed in the form of trading cards, TV shows, movies, and a number of electronic games.

ELECTRONIC GAMES, MORAL BEHAVIOR IN

In February 2002, a neo-Nazi media group advertised the release of *Ethnic Cleansing*, a computer game in which the objective is to kill "sub-humans" (read Blacks and Latinos) and their "masters," Jews. Although this game is an extreme example, it highlights the moral ambiguity that can be found in many electronic games—whether it is expressed through violence, sexism, racism, or anti-Semitism. The controversy surrounding the morality of video game content has been fueled by conflicting research findings regarding the association between game use and gamers' thoughts and behavior.

Trying to shield vulnerable members of society from "negative influences" has been a common response throughout civilization. Compared to adults, young children are less able to distinguish fantasy

from reality, making it particularly disturbing that many games feature fantasies of power and control. On the other hand, video games simply follow a tradition of violent entertainment that has long fascinated the masses, from violent spectacles in the ancient Roman Colosseum to the most violent Hollywood film. In fact, media are often said to reflect the values of a particular society rather than to create them. Video games are no exception, as they are now a major outlet for entertainment for most youth and adolescents in developed countries.

Most research has found a relation (modest in size) between exposure to violent electronic games and aggressive thoughts or behaviors (including a decrease in prosocial attitudes and behaviors). Often, the same data highlight the influence of players' pre-exposure characteristics (e.g., initial levels of aggression or attitudes). If there is any consensus emerging from this research, it is that violent video games may be one risk factor—second to real-world influences, such as bullying, family dysfunction, or drug abuse—that often contribute to "immoral" behavior. To date, no research has found that video games are a primary factor or that violent video game play could turn an otherwise normal child into an immoral individual.

Debates regarding the extent to which video games can impact one's sense of morality will continue to be muddled by an oversimplification of definitions (such as what constitutes moral behavior). Furthermore, inadequate research designs lead to misunderstandings regarding the type of aggression being considered—cognitions or behavior. Is thinking about violence as significant as behaving violently? Finally, the public's tendency to infer causality when the research design precludes such inferences overdramatizes the current literature. This does not suggest that society should not be concerned regarding the moral implications of video game content, especially since certain segments of society have begun to take advantage of improving technologies. For example, the military now uses popular shooting games as training for cadets, desensitizing them to the practice of killing. Extreme groups are also capitalizing on the popularity of video games to recruit new members and spread their messages. Although science has yet to confirm the causal impact of video games on individuals' moral cognitions and behaviors, video games are increasingly being used as vehicles for morally questionable behaviors.

ELECTRONIC GAMES, POSITIVE USES OF

Until very recently, most reported effects of video games on children and adolescents centered on the alleged negative consequences. These included video game addiction, increased aggressiveness, and various medical and psychosocial effects. However, video games have been used innovatively in a wide variety of therapeutic and medical contexts for children and adolescents.

For instance, case studies using video game play as a form of occupational therapy or physiotherapy have been used for diverse groups of people, such as those with learning disabilities, physical handicaps, and emotional disturbances. Innovative uses include the use of video game playing as a respiratory muscle training aid for a young patient with Duchenne muscular dystrophy, and another involving a 13-year-old boy with Erb's palsy who used video game playing as physiotherapy for arm injuries. The playing of video games has also been used in exercise programs to increase hand strength and facilitate the rehabilitation of upper-limb burn victims (using a variety of small to large joysticks). The use of video games in almost all these differing contexts capitalizes on a number of interrelated factors. One of the most important is the child's motivation to succeed. Furthermore, video games have advantages over traditional therapeutic methods that rely on passive, repetitive movements and painful limb manipulation, because video games divert attention from potential discomfort.

One of the reasons video game playing has been used in a number of therapeutic studies is because video games act as "distractor tasks." In one case study, an 8-year-old boy with neurodermatitis was unable to stop picking at his face (particularly his upper lip), and it was causing scarring. All conventional treatments had failed, so, to occupy his hands he was given a handheld video game to play (a Nintendo Game Boy). After just 2 weeks of video game playing, the affected area had healed. In addition to case studies such as this, a small number of U.S. studies have shown that video game playing can provide cognitive distraction for children who undergo chemotherapy for cancer. All these studies have reported that child patients reported less nausea prior to chemotherapy as a result of playing video games. This pain management technique utilizing video games has also been applied successfully to children undergoing treatment for sickle cell disease.

In randomized clinical trials, it has been reported that children and adolescents improved their self-care and significantly reduced their use of emergency clinical services after playing health education and disease management video games. The games have also been used extensively in comprehensive health promotions for adolescents in many areas (e.g., AIDS, alcohol, drugs, sexuality, and smoking).

It is clear that, in the right context, video games can have a positive therapeutic result on a large range of different subgroups. Video games have been shown to help children undergoing chemotherapy, children undergoing psychotherapy, children with particular emotional and behavioral problems (ADD, impulsivity, autism), and children with medical and health problems (Erb's palsy, muscular dystrophy, burns, strokes, and movement impairment).

ELECTRONIC GAMES, RATES OF USE OF

Playing electronic games on personal computers, game consoles, handheld devices, or the Internet is a relatively new but massively popular kind of mediated entertainment, in particular among young people. Boys are generally more active users than girls. The popularity of gaming has gone hand in hand with public expression of worries about game content. Rating systems are operative to inform parents and gamers about the potential harm caused by electronic games.

THE PRODUCTION AND RECEPTION OF ELECTRONIC GAMES

The wide proliferation of electronic games is underlined by figures from the industry. In the United States, game producers reported a steady increase in sales during recent years, from $5.5 billion in 1998 to $7.3 billion in 2004. The picture in the United Kingdom is similar; sales of entertainment software increased from £85 billion in 2000 to £1.34 billion in 2004. The game industry is growing faster than the movie industry and thus has become a serious competitor. The gross market of electronic games grosses more than cinema box office receipts. The movie industry as a total still outperforms gaming, mainly as a result of ancillary revenues such as those from DVDs and sales to TV networks and cable companies.

The audience for electronic games has grown to a massive size since the early 1980s. Many early adopters have continued gaming to the present day. In the meantime, the game market diversified with an increasing number of titles for mature audiences. As a result, the mean age of gamers now approaches 30, a fact emphasized by the industry to underline the wide demographic of gamers and to contradict the common notion that games are designed for children. However, academic research shows that children and (young) adolescents between 8 and 18 years still are the largest audience. Gaming is an attractive pastime for them because it satisfies a variety of needs. The tasks at hand offer challenges at the appropriate level, often in a competitive context. The necessary efforts result in feelings of arousal, both when gamers succeed and when they are frustrated. When the task is completed or the battle is won, the gamer is rewarded

by a satisfying sense of control. In addition, electronic games offer ample opportunities to escape from ordinarily life by fantasizing about one's role in the virtual world. Finally, social needs are satisfied by playing together in real life or on the Internet.

Children and adolescents are genuine multitaskers who often combine games with online chatting and listening to music. It is therefore increasingly difficult to give exact figures about the time they devote to playing electronic games. A combination of industry statistics with data from academic research results in an average of 11 hours per week (about 1.5 per day). Boys are overrepresented among the gamers, and they generally spend far more time on their hobby than girls do.

Recent research reveals that game use is often genre specific. Mark Griffiths and his team found that players of massively multiplayer online role-playing games (MMORPG) are well into their twenties. Other researchers found that first-person shooters (*Doom*), beat 'em ups (*Mortal Kombat*), and racing games (*Need for Speed*) are particularly preferred by young male adolescents. *The Sims* attained its status as the best-selling game ever because of its appeal to both genders and across a range of age groups.

RATING SYSTEMS

The increasing popularity of electronic games has not gone unnoticed. Critical observers publicly expressed their worries about this new pastime. Electronic games were criticized for the ubiquity of violence, the "mean world" they picture, and the stereotypes of women and ethnic minorities. In most countries, rating systems are used to inform parents and other media users about the suitability and possible harmful effects of games. In the United States, the Entertainment Software Rating Board (ESRB) rates electronic games. Pictorials inform parents about the suitability for certain age levels: Early Childhood (3+), Everyone (6+), Everyone (10+), Teen (13+), Mature (17+), and Adults Only (18+). In addition, information is given about each game's content (e.g., cartoon violence, intense violence, animated blood, blood and gore, comic mischief, mature humor, mild language, strong language, and the use of tobacco, alcohol, or drugs). In Europe, since 2003 most countries have embraced a rating system called PEGI (Pan European Game Information), which was issued by the Interactive Software Federation of Europe (ISFE). PEGI labels electronic games with six pictorials that inform their users about the possible harmful effects of "violence," "fear," "sex," "alcohol or drugs," "discrimination," and "bad language." In addition, the pictorials are related to five age categories: "Not suitable under three years," "six years," "twelve years," "sixteen years," and "eighteen years."

Some countries impose legal restrictions on certain games. In Australia, for example, the rating system does not have an 18+ category. Therefore, games with mature content are likely to be banned, as happened recently with *Manhunt*. In the case of *Duke Nukem* and *GTA: Vice City*, the Australian censor required modifications of game content. Another example is Germany. *Return to Castle Wolfenstein* was banned because of German laws prohibiting public displays of Nazism and the swastika. *Doom 1* and *Doom 2* were first banned, but later, modified versions were permitted with, for example, green blood instead of red.

The controversial games are only a part of the mass market of electronic games. The American industry claims that Mature games constitute 16% of the sales, Teen 30%, and Everyone 53%. The 2004 sales charts in the United States and the United Kingdom show a comparable pattern: Mature titles such as *GTA: San Andreas*, *Halo2*, and *Doom3* held top positions, but so did *The Sims2*, the sports games *Madden NFL 2005*, and *FIFA 2005*, and *Pokémon Fire Red*.

ELECTRONIC GAMES, TYPES OF

Electronic games represent a dominant component of children and adolescents' media environment. They serve a variety of entertainment purposes, belong to the important issues of interpersonal communication among (male) peers, and have even established a youth culture and professional competitive structures (e.g., the annual World Cyber Games tournament). Contemporary electronic games are extremely diverse and offer various modes for players to use both alone and together with (many) others. The diversity of games is an important reason for their great attractiveness to children and adolescents, as it allows games to serve different developmental and social needs.

TECHNICAL PLATFORMS AND TERMS

One hardware platform for electronic games is the computer designed only for games, the so-called console. Equipped with a special computer chip to allow vivid audiovisual presentation, the console connects to a television set, which enables game playing in the living room. Sony (Playstation 3), Microsoft (Xbox 360), and Nintendo (Revolution) have dominated the market in 2006. Games played on consoles are typically called *video games.*

The second major platform for electronic games is the personal computer (PC). Special hardware is available for PCs to improve the richness of multimedia presentations. Games played on PCs are typically called *computer games*, although the terms *video game* and *computer game* are often used synonymously.

MOBILE GAMING DEVICES

In 1989, home electronics manufacturer Nintendo launched the first mobile gaming device. The Game Boy was essentially a portable, battery-run game console that allowed play at any location. For years, the Game Boy was extremely popular among children all over the world. More recently, improved models have been developed (Game Boy Advance, Micro) to include better graphics and more complex interactivity. In 2005, Sony launched the Playstation Portable, which is technically the most sophisticated mobile gaming console today; it allows movie viewing and other multimedia functions. In addition to portable consoles, which are primarily dedicated to gaming, electronic games are also available for other mobile devices, such as cell phones, personal digital assistants, and laptop computers (which can run the same games as stationary PCs). Early games designed for mobile playing display comparatively simple task structures (discussed shortly) and require significant dexterity. For instance, players of the *Mario* games for the Game Boy must make the protagonist jump from platform to platform ("jump and run") and must have good timing to avoid traps and obstacles. More recent mobile games are very similar to products sold for stationary use on home consoles and PCs.

OFFLINE AND ONLINE GAMES

Another important distinction in types of electronic games refers to their possible use of the Internet. Early electronic games were played by single individuals offline (single-player mode). Users would play with or against the "artificial intelligence" of the game software that controls dynamic forces in the game world, thus creating challenge and meaningful interaction. The conventional multiplayer mode of video game consoles connects up to four players offline—that is, players use the same console and sit in front of the same screen. PC-based games were eventually programmed to allow for multiplayer use within local area networks (LANs). More recently, PC-based as well as console-based electronic games have begun to include optional connectivity to other players via the Internet. Game manufacturers run Internet platforms to bring players together, hosting a large community of users and enabling multiplayer matches any time, anywhere. For some online games, teams ("clans") have emerged that compete against each other regularly.

The latest development in online gaming is the massively multiplayer online role playing game (MMORPG), described by Elaine Chan and Peter Vorderer. These games are only used via the Internet and require a subscription (e.g., *World of Warcraft*). Players act in large fantasy worlds that represent all users as digital characters (*avatars*). Social interaction between players or avatars (e.g., trading, exchanging hints, making friends) is a major aspect of the entertainment value of such games. The huge realms to be explored and the "development" of the avatar (who gains experience and skills over time) also add to the playing motivation.

ELECTRONIC GAME GENRES

The industry (including game magazines) and academic researchers have developed a variety of genre classifications for electronic games. For instance, www.gamespot.com differentiates action, adventure, driving, puzzle, role-playing, simulation, sports, and strategy. Some widely used game type labels, discussed by Christoph Klimmt (2001), have emerged from those genre lists, such as *first-person shooter* (or *ego-shooter*), *real-time strategy,* and *racing game.* Although frequent players often agree about what kind of game is meant by a genre label, the labels do not meet scientific criteria for object description.

PROBLEMS WITH GENRE CLASSIFICATIONS

The major problem of the genre classifications used in game journals and many scientific articles is that various game properties are mixed implicitly to formulate type labels. For instance, the label *sports games* underlines the narrative dimension of electronic games, whereas *action* refers to the kind of task offered. However, the task structure of a sports game and an action game may be very similar. Other genre labels, such as *role-playing* and *adventure* are only comprehensive if one is experienced with some games that have been categorized this way.

A second problem is that the landscape of available games is changing extremely fast. Every season, new games are published that combine or merge different genres (e.g, *tactical shooters* or combined action and racing games such as *Grand Theft Auto,* which recently have even added components of role-playing games). Conventional game genre descriptions are therefore less informative when it comes to the latest developments in electronic games.

AN ALTERNATIVE APPROACH TO ELECTRONIC GAME CHARACTERIZATION

To address these issues in classification, Klimmt (2001) has suggested basing scientific categorizations of electronic games on dimensional descriptions rather than on fixed (and potentially insufficient) genre labels. According to his approach, electronic games should be portrayed on the dimensions of

- *Narrative framework* (e.g., science-fiction, medieval-fantasy, police story, World War II military), which includes the role that players occupy (e.g., starfighter, sorcerer, detective, soldier).
- *Dominant type of task,* which is most often a specific trade-off between coping with *complexity* (e.g., directing many military units, processing masses of economic information, planning ahead strategically) and acting under *time pressure* (e.g., fighting against fast-acting opponents, building military facilities before arrival of enemy forces, evading traps and obstacles).
- *Perspective of presentation,* which means the way the game world and players' actions are displayed (typical perspectives are "ego-views" of the players' avatars, a "following camera" view that centers the back of the avatar, and a bird's eye view that allows for overseeing multiple units in large geographical spaces, for instance, in strategy games); many games create specific perspectives or enable players to change between different optional perspectives.

CONCLUSION

The quickly changing landscape of genres impedes classifications that are valid over time. Therefore, researchers, teachers, and parents need to make themselves familiar with the diversity and complexity of electronic games in order to resolve the scientific, educational, and social challenges that these games have created for adults as well as for children and adolescents.

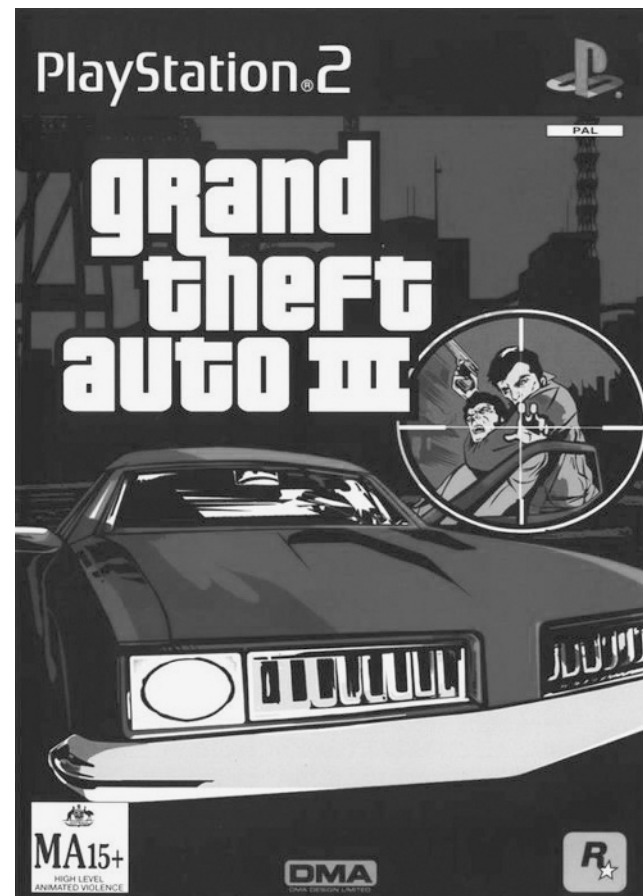
ELECTRONIC GAMES, VIOLENCE IN

In the past 10 years, the content of video games has come under greater media scrutiny as some of the top-selling games have become more graphically intense and violent. The names of these games are now familiar: *Mortal Kombat, Doom, Grand Theft Auto*, and others. Unlike television or film, much of this content remains a mystery to the generation who are too old to be interested in playing these games. Fortunately, a number of content analyses have been done to determine the amount of violence present in video games. Content analyses are particularly helpful for illuminating the types and level of violence found in these games.

Like film, video games come in a variety of genres that delimit each game's themes and content. These genres may be nonviolent (e.g., puzzle games, card games, educational games) or predominantly violent (e.g., shooters, fighters, action). Games in most genres contain a mixture of violent and nonviolent content (e.g., sports, strategy, driving, simulations, adventure, fantasy role playing). For example, sports genre games include boxing, hockey, and



The *Grand Theft Auto* series of electronic games features numerous forms of violence. Players assume the role of a carjacking criminal who can be made to perform a range of antisocial behaviors, from killing police to beating prostitutes to death after having off-screen sex with them. Since the appearance of the first title of the series in 1998, *Grand Theft Auto* has been immensely popular and profitable.

football as well as tennis and golf. Some racing games focus on racing skills (e.g., *Need for Speed, Gran Turismo*), but others award points for running over pedestrians (e.g., *Carmageddon*) or allow players to shoot each other (e.g., *Crash Team Racing*). Although genre is useful for understanding the type of game play, genre designations do little to illuminate the content of games.

Because video games are a comparatively new medium, there are not as many content analyses of game content as there are of movies or television. One of the earlier studies, from 2001, found that 64% of a sample of games contained violence even though they had been rated E (Everyone) by the Entertainment Software Ratings Board (ESRB). The same researchers published a subsequent study of all 396 games released up to April 2001 and found that 94% of games rated T (Teen) contained content descriptors by the ESRB for violence. Content analysis of a subsample of the T-rated games revealed that the same percentage actually contained violence, suggesting the content descriptors found on T-rated games are accurate.

Another set of studies used the National Television Violence Survey (NTVS) content coding scheme to look at the 60 most popular games across three platforms: Sony PlayStation, Nintendo N64, and Sega Dreamcast. The NTVS defines *media violence* as

> any overt depiction of a credible threat of physical force or the actual use of such force intended to physically harm an animate being or group of beings. Violence also includes certain depictions of physically harmful consequences against an animate being that results from unseen violent means.

These studies coded both for the presence of violence and for the context in which the violence is found. Overall, they found that two thirds of games in the sample contained violence, with adult-rated games containing four times as much violence as games rated for children. Games rated for adults were more likely to feature human perpetrators and targets of violence, whereas games rated for children were more likely to contain robot perpetrators and targets of violence. Games rated for adults were also more likely to feature children as perpetrators and were more likely to feature women as both victims and perpetrators of violence than were games rated for children. Adult games contained more justified violence, repeated violence, blood and gore, and gun violence than children's games did. A follow-up study looked at context features of scenes from the first study that contained weapons. It was found that characters using guns in video games were most likely to be male, adult humans intent on protecting life. Game characters using guns were not angry or intent on retaliation or personal gain. Gun violence in games is highly lethal and contains abundant blood and gore. However, the depictions were judged by coders to be generally realistic.

The most comprehensive study of video game content examined 130 games produced in the first half of 2002 for five platforms, including the PlayStation2, Xbox, GameCube, Game Boy Advance, and the personal computer. They found that the game world is significantly more complex than it is often painted by the popular press. The three most common objectives in the game, accounting for about three quarters of games, were to overcome evil (28%); to gain points, as in sports games (23%); and to win a battle (20%). The vast majority of lead characters were male (71%), adult (63%), and of white European background. The largest character types were athletes (21%), followed by soldiers (12%) and drivers (9%). The character played is always the hero of the story and often has special abilities, such as martial arts skills (21%), superhuman powers (19%), or magic (18%). The most frequently used tools were handguns (23%), swords (21%), rifles (14%), and bombs (13%), although only 71% of games contained a character who used a tool.

Another avenue of content analysis has examined advertising messages used to promote the games in large-circulation video game magazines. One study examined 1,054 video game advertisements in regard to the portrayal of gender and violence in the images and text of the ads, as well as the representation of race and ethnicity, the genres of the games, the ratings and labels, and the use of advertising appeals, such as user identification. Results showed that more than half of the game ads contained violence, with an average of 2.5 weapons per ad. Males outnumbered females in the ads by more than three to one.

ELECTRONIC MEDIA, CHILDREN'S USE OF

As long as there have been media, children's content has been offered. Never before, however, has such a vast array of electronic media been targeted toward young consumers. These media include traditional media (e.g., television, radio, and recorded music) as well as computer and wireless media (e.g., Internet, video and computer games, cell phones, personal digital assistants, and instant messaging). Children's use and comprehension of media content change significantly from preschool through adolescence. This entry reviews children's electronic media use in four age categories: young children (0 to 6 years), older children (7 to 10 years), young teens (11 to 14 years), and older teens (15 to 18 years).

Across these stages of childhood, several themes emerge about media use. First, it is clear that this generation of children lives in a media-saturated environment. Ninety percent or more of American homes own a television, a VCR, a radio, a CD player, and a telephone. Nearly two thirds of families with children now own computers and video game players. Second, higher percentages of children report that they own their own media hardware, much of which is stored in their bedrooms. Increasingly, a typical home includes multiple televisions, radios, and CD players. A third theme concerns the environment in which children use media. In many homes, media are on most of the day, competing for attention as family members interact and engage in work and play around the house. Finally, television and music still dominate the media mix in most children's lives. However, the Internet and new wireless technologies occupy a growing portion of children's time, changing the way children deal with information, family members, and their peers.

Studies by the Kaiser Family Foundation, the Annenberg Public Policy Center, and the Pew Internet and American Life Project all document a remarkably consistent picture of this media-laden culture. Children in those studies were reported to spend an average of 6½ hours per day with all media combined. Screen-based media (e.g., television, computers, video games, videos) account for about two thirds of that total. A typical child spends 25 hours with television every week. Those numbers increase when children live in single-parent, minority, or lower-income homes, or with less educated parents. The same is true for what researchers call a "TV-oriented" home, one in which the television is on most of the day (including mealtimes) and in which the parents have few rules for children's television use. This environment has been linked to heavy use of television, video games, and the Internet. These aggregated statistics, however, mask the shifts in children's media use from infancy through adolescence.

MEDIA USE BY YOUNG CHILDREN (0 TO 6 YEARS)

Beginning in the late 1990s, more media programming was targeted at toddlers (e.g., the PBS series *Teletubbies* and various collections of baby sing-along videos). In the limited data collected since, infant and toddler viewing numbers have surprised some observers. On average, they watch 2 hours of TV per day, about half of which is content suitable for adults and teens. Kaiser's surveys found that, on a typical

day, two thirds of toddlers use a screen medium (i.e., television, videos, or computers), and many use more than one per day. Over half of all infants' parents reported that their babies watch television (although with limited periods of sustained looks at the screen). Toddler's dominant media are recorded music, television, videos, and DVDs.

The third year of life constitutes a turning point in children's media use, according to researcher Daniel Anderson. Until that age, children sit facing their parents with their backs to the television, only occasionally looking at the screen while they play. Television-viewing toddlers, at around 30 months, turn toward the television set. Play continues, but with more frequent and sustained attention to the screen. Part of the reason for this change is that cognitive development enables children to understand more content. Undoubtedly, however, this increased attention is due to content that is produced for and marketed directly to children. Programmers are increasingly adept at using color, motion, and sound to capture young viewers' attention, even that of very young children.

During preschool (ages 4 to 6 years), significant increases occur in children's use of all media. As children reach the age of 4, most parents report a peak in viewing television (1 hour per day) and videos (about 45 minutes per day). Video game playing peaks at age 5 at just over 1 hour per day. Further, preschool children are becoming increasingly adept with computers; half or more preschool children can use a computer mouse, load a CD-ROM, and use a computer without a parent's presence. Nearly one third of them have visited websites for their favorite programs or have played with an ever-growing number of software titles designed to fit their computer and academic skills. Nickelodeon, for example, markets software from their popular *Blue's Clues* and *Dora the Explorer* shows that is designed to address reading and math skills.

All told, children up to 6 years old spend 2 hours a day with screen media, with smaller amounts of time on computers. Increased media use has been noted among several groups, including minority homes, families with less educated parents, children in heavy-viewing homes and those with televisions in their bedrooms. Interestingly, though, no clear patterns distinguish boys' media use from girls' use at this age. During these years, however, both music listening and reading (or being read to) remain very popular activities.

MEDIA USE BY OLDER CHILDREN (8 TO 10 YEARS)

Although the mix of media is much the same, average time with each medium increases dramatically during elementary school. Time with screen media alone doubles, and most of it is spent with television. Reports from the Kaiser Family Foundation and the Annenberg Public Policy center indicate that older children spend more then 3 hours a day with television, and nearly 90% of them watch on a typical day. They spend 1 hour per day with audio media, split between radio and recorded music. Equally significant increases occur in older children's use of computers and video games. Game playing peaks during this stage, with about 1 hour per day devoted to interactive game playing online or with video game systems (e.g., PlayStation or Xbox games). Although television remains the dominant medium for older children, increasing amounts of time are spread among other electronic outlets. As with younger viewers, average media time is higher in African American homes and in TV-oriented homes.

Kaiser estimates that older children spend in excess of 8 hours per day with media, although this assumes that children's media use is a linear, singular task. Cognitive development during these years enables children to begin monitoring more than one medium at a time. So, although 6½ hours a day are devoted to media use, a portion of this time is spent with multiple media simultaneously. The beginnings of multitasking surface as, for example, young users listen to music or the radio while playing video games. Starting here and continuing through adolescence, about 25% of children's media time is spent multitasking. Hence, most surveys have found that, after age 8, heavy users of one medium also tend to be heavy users of other media. A parallel here is the increasing array of media in older children's bedrooms, with higher percentages of children owning their own televisions, video game consoles, and computers.

MEDIA USE BY YOUNG TEENS (11 TO 14 YEARS)

Preadolescence and early adolescence mark another turning point in children's media use, particularly in the time they devote to various media. Television use

remains level, but young teens devote less time to home videos, moviegoing, and interactive games. By contrast, young teens' time with audio media (radio and recorded music) and computer use nearly double. Overall time with media, however, remains at about 6½ hours per day, including the time young teens spend multitasking with media. Race differences remain with this age group, and gender differences in the use of some media emerge and stabilize. Boys, for example, are more likely to play interactive games, whereas girls spend more time with audio media, especially recorded music.

Hence, at about the seventh grade (according to the Pew Internet & American Life Project), American children shift to using digital media. These averages of use of various media, however, can mask differences in the *way* children use media. Many of these differences emerge in early adolescence, particularly regarding the content children seek out. A good example is the time children spend with computers. During childhood, nearly all computer time is spent playing games, with slight amounts of time spent Web surfing. Beginning in adolescence, however, significant portions of computer time are devoted to visiting websites and instant messaging systems. Although some of this might be attributable to school-related computer use, a majority of teens' Web surfing is devoted to entertainment and sports sites (i.e., sites related to their other media use). In addition, peer relationships take up more media time as email and instant messaging become frequent modes of interpersonal media.

MEDIA USE BY OLDER TEENS (15 TO 18 YEARS)

Older teens' (ages 15 to 18) media use continues the patterns that surface in preadolescence. Total time with media for 15-to-18-year-olds, according to Kaiser's reports, is 6 hours 31 minutes. Television viewing drops significantly during this stage but remains well over 2 hours per day, more than any other medium. A close second, however, is the combined time that older teens spend with radio and recorded music. Interactive game playing also drops significantly during this stage, and time is instead devoted to computer use (especially online). As with their younger counterparts, older teens devote more time to Web surfing and instant messaging, but their time with email increases tremendously during high school. The result is a media mix in which three outlets (audio, television, and computer) make up nearly three quarters of older teens' media time. Overall, minority teens (African Americans and Hispanics) spend more time with TV, videos, and movies. These populations are also less likely to live in homes with computer and Internet access.

More than any other trend, media use by American teens reflects the coming changes in the digital media environment, according to studies done by the Pew Internet & American Life Project. Whereas about two thirds of adults use the Internet, nearly 9 in 10 teens report going online (half do so on a daily basis). As of 2005, half of teen Internet users had high-speed access, and nearly all of them devoted more time to instant messaging and cell phone use. Furthermore, older teens' online activities more closely mirror Web use by adults. Teen surfers, especially those with broadband access, are more likely to purchase products online as well as to seek out news and health information. Perhaps even more significant is the different media environment in which older teens live. Pew's survey indicates that 86% of teens report that most of their acquaintances use the Internet, and 84% of them own at least one personal digital medium (e.g., laptop computer, cell phone, or personal digital assistant). Media ownership continues to blossom, as three quarters of American teens reported owning their own desktop or laptop computers, nearly half possess cell phones, and a clear majority have television sets in their bedrooms.

EMAIL

An email (originally written *e-mail*, for "electronic mail") is a digitized message exchanged between two or more people using their networked computers. It is now possible to send an email not only to and from desktop computers but also to and from handheld computers, such as personal digital assistants (PDAs), and to and from mobile telephones. Today, a majority of young people in technologically developed countries use email, which can benefit them in their leisure time and in the pursuit of education and careers. However, children and adolescents who use email need both parental guidance and "email competence" to avoid the dangers inherent in email use.

STRUCTURE AND TYPOLOGY OF EMAILS

Email is a service enabling asynchronous communication to take place via computer: Emails go to a mail server before being collected by the recipient at a time of his or her choice, to be read and replied to. There are basically two different types of interface through which an email service can be used from a computer: either through the email program (known as the *email client*) installed on the computer and which downloads the mails from the server, or through a Web browser, to be found on the mail server (known as *webmail*). Webmail enables a user to look in his or her mailbox from any computer with Internet access. It is on the mail server that a user's individual email address is set. Some email addresses afford a clear identification of the user and his or her educational or work setting (an example would be karen.miller@stanford.edu); others afford anonymity (funny_elephant@yahoo.com).

There are usually five parts to an email:

Header: The header of an email serves to record the address of the sender, the address of the receiver, the route followed for transfer of the message, and the date and time of sending.

Subject line: The sender can use the subject line to indicate briefly to the recipient the content and function of the email.

Body: The content of the message is typed into the body of the email. (Technically, any signature or attachments are often also counted as the body of the email.)

Signature: It is possible to arrange for the automatic addition of a "signature" to the body of the email, containing the sender's professional role and postal address or even an epigram.

Attachment(s): It is possible to supplement the content of an email with one or more attachments, which may be documents, photographs, musical excerpts, or video clips in the form of digital files.

There are a variety of criteria for the classification of emails—for instance, their content (private or business) or their function (to inform, to entertain, or to cultivate a relationship). It is possible to differentiate three types of email according to the recipient group:

Interpersonal email: Here, the email is sent to one or more personal addressees (or at least to email addresses), as would be the case when a son sends greetings to his parents and his sister from on holiday.

Mailing list email: Here, the email is sent to a collective address, from which it is automatically distributed to a mailing list for the membership of the relevant group. An example would be a student writing to all the other students at her university via their mailing list.

Spam email (also known as *UBE, unsolicited bulk email*): Here, the email is sent indiscriminately by a person or organization to a large number of Internet users who have neither solicited nor requested such messages. Such emails may contain advertising material, rumors (these are often called *hoaxes*), computer viruses, worms, Trojan horses, corrupt business proposals, or attempts to fish for passwords and other sensitive data. This is known also as *social hacking* or *phishing*.

PREVALENCE AND USE OF EMAIL

Email is by far the most used service on the Internet; the vast majority of Internet users read and write emails regularly. In 2004, a representative telephone survey of young Americans between the ages of 12 and 17 conducted by Amanda Lenhart, Mary Madden, and Paul Hitlin from the PEW Internet & American Life Project, revealed that 87% of those sampled were using the Internet and that, of these, 89% were

sending and receiving emails. The figures for girls as users of email (95%) were higher than for boys (84%), and they were also higher for young people at the upper end of the age range and those from families with higher socioeconomic status.

Interpersonal emails are the electronic counterpart of letters sent by post, which are referred to as *snail mail* in Internet slang. Regular postal mail has been partially replaced by emails in both the commercial and the private spheres because it is much quicker and cheaper to send emails rather than letters. Indeed, email services have caused the frequency and number of written messages exchanged to multiply. Whereas in the past it was customary to send private letters only a few times a year, on special occasions such as at holiday seasons, and for birthdays and anniversaries, many users of the Internet today send several private emails per day, even some to people they have met for the first time on the Internet. Email is an extension of the range of methods of telecommunication available (letters, telephone landlines, mobile telephones, etc.) and tends not to preclude face-to-face communication but to complement it. The sending of disagreeable messages is the only case in which people today tend to revert more frequently to digital delivery (an email or a text message via mobile phone) than to the spoken word, as studies by social psychologists such as Adam Joinson indicate.

Another representative telephone survey, conducted by Amanda Lenhart, Lee Rainie, and Oliver Lewis from the PEW Internet & American Life Project, revealed that young people in the United States tend to prefer email for communicating with adults (teachers, e.g., or relatives at a distance) and for the distribution of a large amount of information to groups, using mailing lists. For day-to-day exchanges with friends and peers, they tend to use instant messaging to organize a rendezvous, discuss homework, and flirt or talk over private matters together. On average, a young American between 12 and 17 years old will spend 10.3 hours a week in the company of friends outside school. A further 7.8 hours per week is spent in contact with friends via various media, among which telephone calls and instant messaging are dominant. Those children and young people who make more intensive use of email also exchange mobile phone text messages more frequently with their friends. In Japan, exchanging emails via mobile telephone is especially popular among young people. Besides contacting email recipients known to them from real life, children and young people also contact others by email—people whom they know only in the virtual world and not in their real identities, for example, because the email address is of the anonymous type. Many users of the Internet today possess more than one email address and use them according to the intention of the current communication.

OPPORTUNITIES OFFERED BY EMAIL

Email gives children and young people an opportunity to extend and intensify their social networks without too high an expenditure of time or money. For example, it is cheaper for them to use email instead of the telephone to manage their contact with relatives living far away or parents living separately. Because the Internet is so widely available in many countries with highly developed technology, young people can easily achieve contact with their peers. The many mailing lists and discussion forums, online games, dating platforms, and so on, provide opportunities to meet new people online both locally and internationally and to cultivate relationships with them so as to achieve friendship or even love affairs. Written exchanges may help reduce shyness and social anxiety, making it easier to meet people and also to have more open and relaxed relationships with friends one already has.

A wide selection of email advice services on health and sexuality is available free of charge to children and young people. There are also online mutual aid groups, in which children give each other support to deal with social or health-related problems, as described by researchers of social work such as Jennifer Tichon and Margaret Shapiro. In addition, teenagers find email valuable for communicating with potential training sites or workplaces, as when asking about practical placements (internships) by email, or sending off job applications in response to electronic job listings or recruitment notices. Particularly for those who live in rural districts, email can widen the radius of children's circles of acquaintance, but the extent to which they make use of it will depend on each child's individual capacities and on the general level of knowledge and training.

Children and young people profit from the provision of email services as part of secondary and higher education. In learning their native language, they can be asked to produce and respond to both snail mail letters and emails—and other forms of digital communication—so that they practice using different

styles with different media. During lessons in other languages, paired classes set up across international boundaries for email purposes can facilitate practical use of the foreign language, thereby increasing motivation. When students conduct a project by means of email with students at other schools (sometimes even internationally), they are effectively receiving training for future work as a "virtual team" in global enterprises. For specific school subjects, relevant mailing lists can be used as sources of information and platforms for discussion, so that the classroom is opened up to possible interaction with the outside world. With guidance, it is possible for pupils, for example, to use email to conduct research, perhaps by sending questions to experts. Within schools and universities, email and mailing lists can facilitate communication between teachers and learners on both the academic and the organizational front.

CHALLENGES OF EMAIL

For children and young people, a number of dangers are inherent in the use of email, which it is appropriate to counter first by guiding and accompanying them and then by teaching them how to develop email competence.

- Depending on their content, *spam emails* may be bearers of many dangers (among them computer virus transfer and the discovery of passwords). In lessons on media use, children and young people should be taught about the varieties of spam, how to recognize them by their email headers, and how to delete them automatically with the help of their email program.

- *Harassment by email* is made easier by the fact that anonymous email addresses are possible. Children and young people may figure among the perpetrators (e.g., in threatening fellow pupils in some way) or among the victims (e.g., in receiving sexualized emails from adults), and they should be made aware of the right and wrong uses of email.

- Although *email friendships* are a way to extend a young person's social network, they bring with them the risk of assumed identities and an illusory closeness. This is particularly true of love affairs by email; within a very short time, intense feeling can develop out of an intimate exchange of emails or online chat. First love for an increasing number of young people is cyberlove. It is thus appropriate to take the significance of these relationships to the young person seriously and to guide him or her in the direction of sensible handling of online relationships—for example, a gradual, safe transfer from email contact to telephone calls and then a face-to-face meeting.

- The phenomenon of *Internet dependence* is present if people use the Internet excessively over a long period with deleterious consequences, such as lack of sleep, reduction of contact with people in the real world, deteriorating academic performance, conflicts with family members, and so on. When children and adolescents are already suffering from low self-esteem, shyness, or loneliness, it can be all the more tempting to escape the anxieties associated with real-life contacts, replacing them with email or online chat and thereby being free both to control and to "improve" one's self-presentation, even to create a fictitious identity (Internet faking). Particular care should thus be taken that children and young people who find contact difficult should not be drawn into damaging dependence on email and online chat.

- There is a *threat to privacy* inherent in email in that communication is quite literally documented in digital form, even when it most intimate. Emails can be monitored by government agencies, email service providers, or parents. Privacy can also be breached when young people forward their friends' emails to third parties. Here again, young people are at risk of being not only victims but also perpetrators.

CONCLUSION

Although email use has many potential benefits, young email users need the guidance and company of parents and guardians as well as formal training in the development of email competence. Empirical studies should be the means of determining the skills and the knowledge that are indispensable to email competence. Such research must always take account of the state of the art in online technology, the state of maturation of the growing child at different ages, the different functions of email as a medium, and the different social contexts in which it is used.

EMAIL PEN PALS

Today, nearly 90% of youth in the United States between the ages of 12 and 17 use the Internet, and about half of these users go online every day. Although instant messaging is extremely popular, email remains the most popular Internet application. Teenagers use email to talk about dating, friends, parents, where they live, sports, school, and other topics. These adolescents not only learn a great deal about each other but also improve their writing skills in the process of writing letters and emails back and forth. Email correspondence between pen pals is a growing part of electronic communication not only for American teens but for young people around the globe.

Indeed, quite a few researchers feel that personal communication not only helps us develop friendships but also is instrumental in learning a language and improving writing skills. Students can learn more effectively when they interact with others because they are able to express ideas and interpret oral and written messages within a meaningful and purposeful context. In doing so, they become familiar with language symbols and structures, which prepares them to make connections between what they know and what they are learning. One activity, pen pal communication, can fulfill these interactive aspects of language development. When two people communicate through writing, an environment for language use is created. This activity has been applied in a variety of educational settings and among students of different age and grade levels. The research findings demonstrate that pen pal writing increases motivation in literacy learning, improves language proficiency, strengthens writing and keyboarding skills, and enhances cultural awareness. In one study, three groups of university teacher-education students were paired with public school students to form pen pal (correspondence through written letters to the university students), e-pal (communication through email to the same teacher-education students), and control (writing to an imaginary correspondent, no response expected) groups. Those students who communicated via email showed the greatest improvement in their writing, as compared to traditional pen pal correspondence. Other schools should consider incorporating e-pal programs so their students can realize these benefits too.

A company called ePALS helps schools set up pen pal communications with students from around the world. ePALS Classroom Exchange is one of the leading providers of school safe email and collaborative technology. Founded in 1986 by John Irving and Tim DiScipio and headquartered in Easton, Connecticut, with offices in Ottawa, Ontario, ePALS is an online

environment in which teachers and students can safely connect with peers in an educational setting. Since it was introduced, ePALS Classroom Exchange has achieved a global reach, with 5.5 million students and teachers in over 191 countries. This reach was achieved by making the site available in English, Spanish, Portuguese, German, Japanese, Arabic, and French. Because students can access potentially illegal content online either intentionally or inadvertently, ePALS introduced ePALS School Mail in 2001. This is a subscription-based, safe email option targeted to schools that allows students to use email in a protected, managed way. Even with safe email, the need to protect students from inappropriate material on the Internet remains and is addressed with the ePALS Safe Browser. The ePALS Safe Browser filters out inappropriate Web content and controls access to computer applications. It is a flexible product that allows school administrators to specify what is "inappropriate" and to create rules for different users, making it a better alternative to other browsers.

There are numerous stories documenting the success of email pen pal writing. For example, Paul McCarty describes a group of sixth graders at his school in Salt Lake City who were experiencing the excitement and wonder of developing pen pal relationships with a group of students from Russia in 1991. They corresponded daily via email for several months, until suddenly messages from their Russian pen pals stopped for several days. The students found out that the military revolution had disabled all channels of information in Russia, and there was no way for the students to connect with their Russian pen pals. The sixth graders were upset and wanted their pen pals to know that they were thinking about them. The American students discovered that the Russians could still receive news items at their school, so the sixth graders uploaded reports of international events relevant to the Soviet Union onto an electronic news service, hoping that their Russian pen pals would know that it was their American pen pals who were sending these news stories. After 4 days without communication, the people of the Soviet Union once again had access to regular Internet news channels and were able to communicate with the rest of the world. McCarty used this class project to study the effect of interacting with students from another country and found that pen pal communication enhanced the students' cultural awareness in addition to improving language literacy and writing skills.

In another study, Ping Liu examined the impact of a cross-cultural pen pal writing project between a group of second graders in the United States and one in China on students' learning experience and cross-cultural understanding. Liu found that the email correspondence between the two groups of second graders significantly impacted their school learning experience and enhanced cross-cultural understanding. The students were excited about the pen pal project, and this excitement fostered a desire to learn more about each other. They discovered some similarities between the two classes, such as the subjects they studied at school, the games they played outside, and their favorite sports. And they were amazed at some of the differences—for example, the Chinese class was large, with 65 children, and the Chinese children were responsible for keeping their classroom clean. As a result of this cross-cultural experience, the American second graders set up a program in which students picked up trash and cleaned up their classroom. The second graders also expressed a desire to understand Chinese, and they learned to write the Chinese characters for a variety of words, including those for *tree*, *stream*, and *sun*. These studies show that email pen pal communication is an integrated activity that has the potential to influence students' cognitive, linguistic, social, cultural, and affective development.

ENGAGED RESISTANCE

Engaged resistance is a term coined by a group of citizens, the Motherhood Project. It denotes the attempt to minimize the worst effects of mainstream or dominant culture through acts of individual or familial initiative, such as curtailing the number of hours the television is on or boycotting a particular vendor, combined with acts of civic engagement, such as collectively pressuring advertisers or petitioning corporate CEOs or public officials.

Popular culture in late-20th- and early-21st-century America has clearly become an increasingly potent force. Many observers, from parents to social critics, express worries about the power the media has gained over everyday life as well as the extent to which earlier forms of authority—-even the limited authority of individualism—have eroded. In her book *The Plug-In Drug,* for instance, Marie Winn expressed her dismay about the displacement of traditional modes of socialization by the mass media, arguing that the extensive viewing of television by children has a potentially disastrous effect on their psychological development. From Neil Postman to Jerry Mander, media critics have written with alarm of the effects of the media on the social world and inner functioning of children. Psychologists and others agree that everyday bonds with people and places play a crucial role in the formation of children's intellectual, creative, emotional, and spiritual well-being.

Worries about the influence of new forms of media technology have been largely drowned out by promoters and beneficiaries of the high-tech boom of the 1990s and those rapt consumers eager to embrace what seems to them to be unstinting progress. Dissent has often taken the form of objections to overly explicit sexual and violent content in particular genres, from daytime and prime-time television programs to movies, music lyrics, and video games. For some groups and individuals, however, these objections are a launching pad for their broader resistance to the role of popular culture in socialization.

One of the most noted critics of explicit sexual and violent content in music lyrics was Tipper Gore, wife of Al Gore, vice president and then Democratic presidential nominee in 2000. In the mid-1980s, when her husband served as senator, Tipper Gore became aware of the widespread impropriety in popular culture forms aimed at children and put forth her views in testimony before Congress. In 1987, she published a book called *Raising PG Kids in an X-Rated Society,* helping to set the groundwork for the uniform labeling system for music CDs instituted in 1990 by the Recording Industry of America. As a result, some CDs were rated "Parental Advisory—Explicit Lyrics." Gore and others drew attention to the inappropriate content of many television shows, video games, Internet sites, music videos, and advertisements, as well as music lyrics. In her book, she argued against censorship but in favor of "individual and community action" as a way to get across shared moral standards.

By the year 2000, it had become clear to many that the new rating systems for music CDs, like those previously inaugurated for movies, did little to diminish the overpowering effects of popular culture messages that often violated even minimal standards of decency. Parents, in particular, lamented the inescapability and callousness of the messages purveyed by the popular culture, messages they often thought were the opposite of what they tried to get across to their children through example and instruction. A chorus of objections arose from a number of different quarters. The Parents Television Council, a conservative Los Angeles-based group, lobbied for social responsibility on the part of the entertainment industry in part through complaints to the Federal Communications Commission. Another citizen action group was Action for Children's Television, founded in 1968. It achieved some limited success, through, for example, petitions to the Federal Communications Commission and the Federal Trade Commission advocating restrictions on advertising—that is, until the 1980s movement toward deregulation. Still other organizations—the National Coalition on Television Violence, the National Citizen Committee for Broadcasting, the Coalition for Better Television, to name just a few—launched public education campaigns, threatened boycotts of programs and producers purveying offensive content, and pressured advertisers to boycott particularly abhorrent programs.

The usual response to public outrage, however, was usually two-pronged: Some cited the First Amendment

as a rationale for an "anything goes" mentality, whereas others insisted that oversight of the images and messages to which youngsters are exposed is the sole responsibility of parents. Parents largely agreed that the lion's share of responsibility fell on their shoulders, and many turned to ratings systems and watchdog publications to help them determine what fare was acceptable. Some turned to character education and home schooling to counter what they saw as the sickly—even immoral—mainstream culture. In 1996, the Telecommunications Act mandated that televisions be equipped with a V-chip, a device that allows parents to program their sets to block certain content.

Although many parents are vigilant about what their own children hear and see, many argue that they are unable to monitor an entire culture. The omnipresence of media technologies and the popular culture make it nearly impossible to guard against their ill effects single-handedly. This inescapability of culture has prodded some groups to take an all-embracing and activist approach that combines individualistic and more collective resistance to the dominant entertainment style and content.

The Motherhood Project, led by Enola Aird of the Institute for American Values, is an organization that strives to counteract what it sees as the less-than-salutary messages and imagery rife in American popular culture. Including but transcending particular instances of offensive content, the organization's animus is to take issue with the exploitation and manipulation of children through marketing in general. The Motherhood Project presents a model of civic involvement over issues of shared public concern. It urges families and individuals to take responsibility and make changes, from reducing the time spent watching television and playing video games and the like, to muting advertisements when they come on, finding alternative forms of entertainment, and refusing to purchase clothing adorned with advertising logos. It also furthers collective protest, urging citizens to pressure or boycott companies purveying antisocial messages through their products or those that sponsor explicit sexual or violent programming. The Project encourages petitioning and letter-writing campaigns, lobbying, and the formation of "communities of resistance" and considers this multifaceted approach engaged resistance.

ENTERTAINMENT-EDUCATION, INTERNATIONAL

Entertainment-education (E-E) is a communication strategy to bring about behavioral and social change. E-E is the process of purposely designing and implementing a media message to both entertain and educate, in order to increase audience members' knowledge about an educational issue, to create favorable attitudes, to shift social norms, and to change overt behavior. Its general purpose is to contribute to the process of directed social change, which can occur at the level of an individual, a community, or a society. *Takalani Sesame* and *Cuando Estamos Juntos* are examples of E-E—from South Africa and Latin America, respectively—directed to children and adolescents.

TAKALANI SESAME

Kami is a mustard-colored, furry, bear-like muppet sporting a mop of brown hair and a beaded blue vest.

She loves nature, telling stories, and playing with children. Kami's parents died when she was young, and she is HIV-positive. In 2002, Kami, the muppet, joined the cast of *Takalani Sesame,* South Africa's version of *Sesame Street,* to help 3-to-7-year-olds (and their families) understand HIV and AIDS, including ways to cope with it. *Takalani* means "be happy" in the local Venda language, and Kami's name is derived from the Tswana word for acceptance. In a world where HIV-positive children are often isolated, demonized, and victimized, Kami symbolizes a message of hope, possibility, and understanding. *Takalani Sesame* is one of the most popular television programs among children in South Africa.

CUANDO ESTEMOS JUNTOS AND *DÉTENTE*

In 1986, a unique communication project targeted to young people was launched in Spanish-speaking Latin America. Johns Hopkins University's Center for Communication Programs and local in-country partners produced two rock music songs, a highly popular genre among teenagers, promoting teenage sexual responsibility, *Cuando Estemos Juntos* (When We Are Together) and *Détente* (Wait). *Cuando Estemos Juntos* was number one on popular music charts within 6 weeks of its release in Mexico, and soon it was a top-rated song in 11 other Spanish-speaking Latin American countries. In *Cuando Estemos Juntos,* the teenage singers told their audience not to have sex. Using the song to communicate this message was a much more effective strategy than having a preachy message emanate from parents or priests. The typical Mexican radio station played *Cuando Estemos Juntos* about 14 times *per day* for the 4 months of the song's greatest popularity. *Détente* was a more typical hit song and was played "only" 5 times per day for several months. Thus, listeners were repeatedly exposed to the educational content of these rock music songs.

HOW E-E CONTRIBUTES TO SOCIAL CHANGE

The entertainment-education strategy contributes to social change in two ways. First, it can influence audience awareness, attitudes, and behavior toward a socially desirable end. Here, the anticipated effects are located in the individual audience members. One example is the Tanzanian radio soap opera, *Twende na Wakati* (Let's Go With the Times), which convinced several hundred thousand sexually active adults to adopt HIV prevention behaviors (such as using condoms and reducing their number of sexual partners). Second, the E-E strategy can influence the audience's external environment to help create the necessary conditions for social change at the system level. Here, the major effects are located in the interpersonal and sociopolitical spheres of the audience's external environment. The entertainment-education media can serve as social mobilizer, advocate, or agenda-setter, influencing public and policy initiatives in socially desirable directions. For instance, the popular South African television series *Soul City* mobilized community action and women's marches, and it speeded passage of domestic violence legislation in South Africa through media, public, and policy advocacy.

FORMATIVE, PROCESS, AND SUMMATIVE RESEARCH IN E-E

E-E projects benefit from formative, process, and summative research. Formative evaluation research is conducted with the intended audience in order to design the entertainment-education intervention.

Formative research is conducted while an activity, process, or system is being developed or is ongoing, in order to improve its effectiveness. Research-based information about the characteristics, needs, and preferences of a target audience sharpens the design of entertainment-education. For instance, in the South African E-E series *Soul Buddyz,* directed to children 8 to 12 years old and their families, messages about self-esteem were built around ethnic, gender, and socioeconomic lines. Formative research showed that children who were "different" in any way were teased and bullied by others. The self-esteem message was continuously conveyed through the composition of the *Soul Buddyz* friendship group, which included people from different racial and socioeconomic backgrounds with different abilities but who were friends and supportive and respectful of each other.

Entertainment-education interventions are further strengthened through such *process evaluation activities* as the analysis of audience letters, monitoring of clinic data (to track family planning adoption, for example), and content analysis of the entertainment-education messages (to determine whether scripts are consistent with desired educational goals). Feedback can thus be provided in a timely manner to entertainment-education media producers for appropriate mid-course corrections.

Summative evaluation research measures the effects of the entertainment-education campaign on audience behavior. For example, an E-E radio soap opera *Tinka Tinka Sukh* (Happiness Lies in Small Pleasures), which promoted the education of girls in Hindi-speaking north India, was evaluated by a field experiment (using pre- and post-treatment and control audience surveys), content analysis of the episodes and of listeners' letters, and a case study of one village in which the program had strong effects.

E-E'S PROMISE AND DILEMMAS

By 2005, several hundred E-E interventions have been implemented, mainly for health-related educational issues, and many directed at children and young people, especially in the developing countries of Latin America, Africa, and Asia. Research evaluations of the E-E strategy suggest that such programs have the potential to engage audience members, earn high audience ratings, and also serve their social development goals.

However, the use of the E-E strategy necessarily involves ethical dilemmas. For instance, is it right to use the mass media as a persuasive tool of social change? Also, who decides what represents a desirable prosocial behavior? It might be hard to argue against the educational value of E-E programs that promote HIV prevention; however, for certain other issues, such as promotion of condom use among youth, arguments can be made for different positions. Some may argue for the value of protecting teenagers from sexually transmitted diseases, yet others may argue that free availability of condoms promotes teenage promiscuity.

ENTERTAINMENT-EDUCATION IN THE UNITED STATES

Entertainment-education (E-E) is the planned use of entertainment media to communicate prosocial messages to mass audiences. It differs from standard informational programming and public service announcements in that it is typically higher in entertainment value. Unlike international efforts in E-E, in which media programs are often written and produced with the prosocial message in mind, in the United States most E-E messages are embedded in existing television programs. Thus, the message is developed to fit into the existing narrative. Although it has been successfully employed in international efforts, E-E programs have not been used widely in the United States. When they have been used, they have been used to educate the general public on a wide array of issues, such as children's immunization, adolescents' sexual health, and literacy.

Characteristics of the American media market, such as media saturation and the for-profit industry, pose unique problems for E-E efforts. In international efforts, there is little competition for the audience's attention because there are so few media markets. In contrast, in the United States an individual television program has much competition. Many popular TV programs are watched by fewer than 20% of American households. Further, the American media industry is a highly profitable business, and some scholars have argued that campaign designers may find it difficult to convince the industry to include prosocial messages that have the potential to lower entertainment value.

Despite these obstacles, most scholars agree that E-E programs have existed in the United States since 1969. Three early efforts of E-E deserve mention: *Sesame Street, Happy Days,* and the Harvard Alcohol Project's Designated Driver Campaign. *Sesame Street*,

a popular children's education program, is widely recognized as the first E-E television program in the United States. Developed in 1969 by the Children's Television Workshop, *Sesame Street* has been found to affect children's knowledge and behavior. Specifically, children who watch *Sesame Street* are more likely to spend time reading than those children who do not watch *Sesame Street.* In the 1970s, *Happy Days* was successful in disseminating a prosocial message through one of its episodes. In the episode, one of the lead characters, Fonzie, went to the library and ended up getting a library card even though his original intent was to pick up girls. After the show was aired, library card ownership increased. In 1988, the Harvard Alcohol Project partnered with the media industry to promote the use of designated drivers in one of the first coordinated E-E campaigns in the United States. The campaign included spots on television programs watched by adolescents, such as the hit TV sitcom *The Cosby Show.* The project's campaign is credited with being a catalyst in changing social norms for drinking and driving.

In more recent years, national organizations such as Hollywood, Health and Society, the Media Project, the Kaiser Family Foundation, and the National Campaign to Prevent Teen Pregnancy (NCPTP) have worked with television writers and producers to include health messages in television programs popular among adolescents. These organizations also provide scriptwriters and producers with tip sheets on coverage of health issues via their Web pages. Healthy messages have been embedded in such popular programs as *ER*, *Friends, Dawson's Creek,* and *Everwood* and in teen magazines such as *Teen People.* For example, the NCPTP worked with the writers and creators of *Everwood* to include a teen pregnancy story line for one of the show's lead characters.

E-E programs have been found to be effective in the United States, although scholarly work evaluating such programs is rare. The popular television program *Friends* included a sexual health message that focused on the ineffectiveness of condoms, in which one of the main characters repeated that condoms are "only 97% effective." A study conducted by Rebecca Collins and her colleagues found that the majority of the young-adult viewers (65%) of this *Friends* episode were more likely to remember the sexual health message and 6 months later were more likely to accurately report the effectiveness of condoms than young adults who did not watch the program.

Many mass communication theories are relevant to the study of entertainment-education efforts, but two theories are especially relevant. Most scholars analyzing E-E effects base their analysis in theories of media effects, such as social cognitive theory. According to social cognitive theory, the more a person identifies and relates to a character on television, the more likely the person is to model that character's behavior. The theory of parasocial interaction, which posits that individuals build quasi-interpersonal relationships with characters in the media, is also relevant. According to this theory, a viewer is more likely to remember and appropriate the behavior modeled in a prosocial message if the viewer has formed an attachment to the character.

ETHNICITY, RACE, AND MEDIA

Children and adolescents can learn about diverse racial and ethnic groups and their cultures from media presentations. Most media provide stereotypic images of groups other than European Americans. There are infrequent examples of positive interaction between members of diverse groups. Media portrayals influence children's racial and ethnic attitudes, knowledge, and perceptions about all racial/ethnic groups, including their own. Although mass media stereotypes recur, the media have the potential to provide content that could promote increased cultural knowledge, positive racial attitudes, and appropriate models for how to live, work, and play together in a diverse world.

African, Asian, European, Hispanic, and Native Americans have unique histories of inclusion or exclusion from various aspects of American society. Mass media perpetuate messages about the role of race and ethnicity in society by offering vicarious experiences with diverse individuals who may otherwise be unavailable to the viewers. Because mass media are powerful and ever-present in the lives of youth, adults wonder about the extent to which media contribute to the maintenance of stereotypes and prejudice or, conversely, the extent to which they provide children and adolescents with important, positive messages about living in a multicultural society. The influence of mass media may be more potent as many youth continue to live in neighborhoods and attend schools that are racially and ethnically segregated. Since the 1920s, researchers have examined the extent to which diverse racial/ethnic groups were (1) *recognized by* or included in mass media and (2) *respected* by the roles and portrayals assigned to them.

EXPOSURE TO DIVERSE MEDIA CONTENT

Racial and ethnic characteristics influence how youth utilize media. African, Hispanic, and Native American youth watch more television than do European Americans. Hispanic youth watch more cartoons, whereas European American youth watch more educational television. Asian American youth have the highest Internet usage, and African American teens play more video games. Within each medium, children and adolescents expose themselves to different diets of racial and ethnic content. For example, African and European American youth have greater preferences for music and television that feature same-race characters. In a study of favorite television programs, white teens preferred homogeneous, same-race television programs, and black teens preferred programs that included African American characters. The viewing habits of the two groups were so different that few European Americans watched any of the 10 favorite shows of the African Americans, and vice versa.

RACIAL AND ETHNIC PORTRAYALS IN MEDIA

Visible racial and ethnic groups are underrepresented and stereotyped in mass media. They are segregated in specific types of content, on specific days, and even on specific media outlets. For example, Hispanic Americans are limited to situation comedies and reality crime shows. African Americans are largely confined to the lower-rated networks such as UPN, same-race situation comedies, and the nights of lightest viewing, Monday and Friday. The racial segregation is so specific that a study of Saturday-morning children's programming showed no examples of minority females on three of the four major networks. Generally, advertising and educational programs provide greater recognition for diverse groups than do prime-time television programs. Despite the success of individual celebrities, currently there continues to be no example of a prime-time, noncomedy television program that features a lead actor who is not European American.

Portrayals of diverse groups are limited, with visible racial and ethnic minorities presented as more homogeneous and less differentiated than European American characters. Repeatedly, whites have a wider range of roles and portrayals across a range of media content, including all types of advertising. For example, although African, European, and Latina/o Americans are portrayed as police officers and court officials in crime and justice television programs, including reality-based police shows, African Americans are more likely to appear as perpetrators of crime in local and network news programming. A similar pattern of limited portrayals relying on racial and ethnic stereotypes can be found in media as diverse as cyberspace websites, Disney animated feature-length films, and magazines.

Relationships across racial groups on television are infrequent and generally do not include close, intimate, and positive relationships between European Americans and members of other groups. There is greater cross-racial interaction on children's and educational television; the interactions are positive or neutral. However, issues of race are rarely discussed. Cross-racial interaction typically includes whites, a fact that suggests that groups of nonwhites alone do not work or are not important enough to be recognized. In fact, televised youth portrayals are more often associated with conflict between members of the same race than between members of different racial groups. The Internet, with the proliferation of content that focuses on racial and religious hatred, provides disturbing messages that interracial interaction is undesirable and should be avoided.

EFFECTS OF DIVERSITY IN THE MEDIA

There is no doubt that children learn about people from television. Children of all races agree that on television there are racial differences in how roles are presented, with European American characters more likely to appear with positive characteristics and members of other groups more likely to have negative characteristics. Children of all races will select diverse individuals as people they admire, although white children are more likely to choose same-race television characters and celebrities as their favorites. Generally, youth evaluate portrayals of same-race characters as less realistic than portrayals of different race groups. Children with prior personal experience with people from other groups evaluate portrayals as less realistic than children without diversity experiences.

Media presentations can affect attitudes toward diverse groups. Negative racial portrayals are linked to negative racial attitudes, and positive portrayals are associated with more positive attitudes. For African Americans, the relationship between the nature of black portrayals and subsequent attitudes is more complex, in part because of differences in racial identification and prior experience. These variables can result in diverse interpretations of the racial/ethnic content offered, making prediction of the effect on same-race attitudes difficult. Racially diverse models have the potential to influence behaviors, as youth will observe and imitate both same-race and cross-race models. When examples of positive interracial interaction in educational television were provided, children's interest in cross-racial friendships was increased, and positive feelings toward diverse groups were enhanced. Additionally, planned media interventions to improve race relations, including episodes from *Sesame Street* and from the anti-racism video series *Different and the Same,* indicate the potential of media to help children effectively interact with people from diverse racial and ethnic groups.

ETHNICITY/RACE, MEDIA EFFECTS ON IDENTITY

Racial and ethnic minorities in the United States experience prejudice and discrimination, and these experiences affect how children and adolescents think about themselves. Despite the myth of a the United States as a "melting pot" in which the identities of diverse racial and ethnic groups are hypothesized to dissolve into single American identity, children and adolescents define their sense of self in relationship to their ethnic/racial group membership. Because mass media reflect the values of the larger society and offer examples of what it means to be an adolescent with particular social characteristics, researchers have

studied how mass media influence the development of racial or ethnic identity.

DEVELOPMENT OF RACIAL/ETHNIC IDENTITY

Identity, a multidimensional sense of personhood that is shaped by internal and external factors, provides the sense of uniqueness that every human being experiences. According to Erik Erikson, identity formation is a developmental task in which the adolescents are required to decide who they are, what roles they will play in the world of work, and how they will engage in intimate relationships within specific cultural and social forces. Because identity development occurs in relationship to others and in response to others' reactions to the individual's thoughts and actions, media has the potential, over the course of the developmental cycle, to affect identity development.

According to Margaret Spencer, racial or ethnic identity is multidimensional and includes both a sense of self and identification with a reference group. Because these two components can operate independently, racial identity—one's attachment to and feelings about a group—is separate from one's sense of self and self-worth. Racial identity can take different forms: (1) An individual may identify *as* a member of a group; (2) an individual may identify *with* members of a group; or (3) others may *assign* an individual to a group, although not all three options are equally available to members of specific racial or ethnic groups. William Cross and others suggest that racial identity may develop over time and may change its content as an individual reacts to societal messages about and experiences with the role of the reference group in the larger society. The importance of racial/ethnic identity is influenced by one's context, including the racial/ethnic composition of specific settings and the attitudes of the participants in those settings. In particular, media are important sources for identity development, as they present examples of "hip" teen models and redundant messages about racial groups that may influence a child's values, behaviors, and expectations.

MEDIA EFFECTS ON RACIAL/ETHNIC IDENTITY

Youth of all groups are exposed to recurring, consistent, and normalized stereotypes of visible racial and ethnic minority groups in the media. Although adolescent consumption of this content varies, coviewing with peers helps to solidify media selections and amplify the differences in media choices between teen groups. For example, African American and European American youth have a strong preference for media featuring people of the same race, with African American girls selecting more same-race music and European American girls selecting more same-race television programs. Despite these preferences, adolescents are exposed to some media featuring racially diverse casts.

Racial identification can affect the selection of media content leading, for example, African American teens with strong racial identities to be more likely to select media featuring same-race participants than are African American teens with weak racial identities. As teens in general use media to help bolster their social identities, it is not surprising that African American and Korean American teens, for example, report using the media to help form their racial/ethnic identity. For some, like African American teens, the tendency to pick same-race content is not dependent on the nature of the television. Because the reference groups of most adolescents of color are undervalued by society, there are three possible reactions: (1) If they accept group membership as a personal fault, media presentations may negatively influence racial identity; (2) if they are proud of their group and reject the majority culture, media may strengthen their positive identification with media featuring their reference group; or (3) if they deny group membership, they may avoid exposure to media featuring the group. Although these alternatives are available to African American youth, the possibilities for diverse media sources to support positive identity development for Asian American, Latina/o, and Native American youth are severely limited by their restricted inclusion on the dominant media. According to Federico Subervi-Velez, Latina/os have additional media choices to support their ethnic identity: They can choose to engage with Spanish-language television developed by Latin American sources. In fact, little is known about the role of the media in racial and ethnic identity development in adolescents.

Research with children suggests that television can affect the racial/ethnic identity of children and that children's racial/ethnic identity affects their television use. Television programs such as *Sesame Street* and the multiethnic animated series *Superfriends* had positive effects on racial identification such that children had

higher levels of identification with same-race characters and recalled more information about the cultural features and activities of same-race characters than they did for different-race characters. There is evidence that, for African American teen girls with strong racial identities, exposure to mainstream television does not negatively affect body image. In fact, exposure to black programs was associated with better body image, contrary to the effects of this medium on white teen girls. Similarly, African American adolescents are more likely to rate same-race characters as more similar to themselves than other-race television characters. There is much less information about the impact of racially diverse media on other racial/ethnic groups. In research on smoking cessation, for example, Hispanic teens who watched more ethnic programming, a sign of strong ethnic identification, exhibited decreased ability to make friends without using tobacco. This result is difficult to explain but provides a bit of information on the relationship between media, race/ethnicity, and identity. Despite limited research on media effects on racial/ethnic identity, there is ample evidence that media contribute in important ways to the development of gender identity, sexual behavior, and occupational choices.

ETHNICITY/RACE, STEREOTYPING

How individuals from different racial and ethnic groups are portrayed in the media has generated considerable scholarly attention, with research over the decades reporting a great deal of variability—in the ways that portrayals have changed over time and in the ways different ethnic and racial groups tend to be characterized. In general, although research suggests that some stereotypes are less common than has been typical in the past, numerous stereotypes continue to exist in a variety of media content, including content aimed specifically at children.

PORTRAYALS OF RACE/ETHNICITY

The inclusion of people of color in media programming has undergone dramatic changes over the decades; some racial groups now appear in numbers that approximate population percentages, yet other groups continue to be largely nonexistent in the television landscape. For example, Robert Kubey's content analysis of characters on network and cable stations found that white characters accounted for 81% of all appearances, African Americans, 11%, and Latina/os, 7%. Asian and American Indian characters continue to be vastly underrepresented.

Similar patterns in portrayals are observed in media content directed specifically to children, with many cartoons featuring few or no minority characters. These patterns are also observed in other types of content, including comic strips, commercials aired during children's programming, and video games, in which minority characters are atypical or are included as only minor characters or in background roles.

In addition to noting the frequency of minority portrayals, researchers have examined demographic characteristics, behaviors, and traits associated with depictions of race. For example, earlier research reported that entertainment television tended to

characterize minorities as impoverished, uneducated, and lower class. However, more recent content analyses have reported fewer differences between black and white characters in terms of portrayed income. In addition, other researchers have suggested that Asian characters now tend to be portrayed as "model minorities," working in such fields as law, education, and health care. Despite these findings for entertainment, however, content analyses of news portrayals have reported that African Americans continue to be disproportionately associated with poverty.

The distinction between entertainment and news programming is also evident in terms of portrayals of crime. That is, whereas content analyses of fictional programming have tended to report small or nonexistent differences in crime involvement or antisocial behaviors between different minority groups, analyses of news programs or "reality-based" police programming report that minorities (and particularly African Americans) are disproportionately shown as criminal suspects and are portrayed in ways that imply that they are particularly dangerous or aggressive.

Surprisingly little research has explored the nature of stereotypical portrayals of child characters or of programming content aimed specifically at child audiences. Arguably, the greatest research attention in this regard has focused on commercials and advertising, with recent analyses suggesting that this content continues to feature stereotypical portrayals. For example, Meredith Li-Vollmer's analysis of television commercials targeted to children reported that white characters were more likely than minorities to be shown as professionals; African Americans as service workers, athletes, or musicians; Asian characters as associated with high-tech products; and Latina/os as workers in restaurants. Of the little research that has been conducted on entertainment programming specifically, one general conclusion is that, when minority characters are prominently featured, they tend to be on shows that feature casts of primarily a single race (e.g., *Fat Albert*). One implication of this pattern is that media content rarely features interactions between white and minority characters.

One notable exception to the stereotypical portrayals found in commercial and programming content aimed at children is entertainment-education programming. For example, *Sesame Street* features a diverse cast of characters, including both adults and children. In addition, this program includes specific segments designed to teach children about a variety of cultures, races, and languages associated with racial and cultural groups that are infrequently seen in other types of television content (e.g., American Indians).

EFFECTS OF PORTRAYALS

Research on the ways in which media stereotypes may affect viewers' attitudes, beliefs, and behaviors has tended to focus on harmful outcomes, although some research (particularly with children's programming) has explored the idea that positive portrayals may hold the potential to increase favorable attitudes among whites toward ethnic minorities. With this in mind, however, the majority of social scientific studies suggest that media stereotyping can result in increases in stereotypical beliefs, can affect judgments of individuals in ways that reflect prejudicial attitudes, and can prime stereotypical thoughts. For example, studies suggest that heavy viewing of programs such as crime shows and news is associated with beliefs that African Americans are more impoverished and more heavily involved in crime than are whites. Similarly, experimental research has demonstrated that viewing media stereotypes can "prime" or "activate" stereotypical thoughts that, in turn, affect not only judgments or perceptions of subsequently viewed media but also judgments of individuals encountered after viewing. Finally, research on viewers' selection and interpretation of media content has reported a tendency for viewers to perceive portrayals of race as consistent with their existing stereotypes.

In contrast to these harmful effects of media stereotyping, research on prosocial content suggests that positive and inclusive media portrayals have the potential to result in beneficial outcomes, particularly among children. For example, studies of the effects of educational programming such as *Sesame Street* suggest that the viewing of such programming not only can increase favorable feelings toward minority groups among white viewers but also can increase feelings of confidence and pride among minority viewers.

The combination of findings on the nature of media stereotypes and research on the effects of stereotypical images is cause for concern. However, as the media landscape slowly changes to reflect more equitable and favorable images, and as researchers continue to explore ways to harness and increase prosocial aspects of media viewing, perhaps the current bleak situation

will become one in which racial diversity is celebrated both in the media and among its viewers.

EUROPE, MEDIA USE IN

Because the name *Europe* refers to different geographical, cultural, and political spaces, statistics on European media use also refer to varying regions. Reference is often made to the European Union (EU) and its current 25 member states: Austria, Belgium, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom. Focusing on this group of countries makes it easier to describe the European media landscape because these states have agreed on some common principles regarding their media systems, and there are more advanced comparative statistics on this level. Because of their close cultural, political, and economic relationships to the EU, Norway and Switzerland are often included in European statistics. In addition, there are many countries in eastern and southeastern Europe that belong to the wider understanding of Europe; these include Russia, Belarus, Ukraine, Moldavia, Romania, Bulgaria, Croatia, Bosnia-Herzegovina, Serbia and Montenegro, Macedonia, Albania, and Turkey.

TRANSNATIONAL MEDIA IN EUROPE

Despite recent trends of globalization and European integration, the European media landscape is still divided along national and cultural boundaries. One important reason for the continuing predominance of national or even regional and local media is the plurality of languages in Europe. Even among the 25 member states of the European Union, there are 19 different national languages and an additional number of regional languages. On the basis of the numbers of native speakers, German, English, French, Italian, and Spanish are the most important languages. For international communication, English is by far the most important language; around 50% of the people within the European Union are able to understand English. However, this does not mean that these people use English-language media. Thus, in general, the European media landscape is strictly divided by language barriers.

Beyond this general rule, only a few European media outlets target transnational European audiences. In television, the most important examples are

Eurosport, a commercial sports channel, Euronews, an initiative by several public broadcasters to offer a transnational news channel, and the commercial music television station MTV, which offers several versions of its programming for different parts of Europe. MTV has been particularly important for young people in providing current pop music, stories about famous pop idols, and innovative entertainment formats for young people.

Although dedicated transnational media do not play a significant role in Europe, there are other ways to distribute international content to children and young people. The most important one is international pop music as distributed by music television, by hit radio stations, and via the Internet. In this respect, European children and adolescents tend to follow international trends; with the exception of some outstanding stars, they do not prefer the respective national music. The other kinds of international content are movies, television series, and television entertainment programs. As throughout the world, a large amount of programming on European television and movie theaters is imported from the United States; according to the European Audiovisual Observatory, U.S. imports constituted about two thirds of the overall imports of television fiction. Thus, for example, German or French viewers are much more likely to see American movies or series than Spanish or British movies or series. This general rule is also true for children's programs: All European children know Disney and other American productions; more recently, the globally distributed Japanese anime formats like *Pokémon* and *Dragonball* have become familiar to many European children. So far, there has been only limited exchange of children's programs within Europe; however, the European Broadcasting Union and its Working Group for Children's Programmes have set out to further international co-productions and exchange between the public broadcasters in Europe.

An important aspect of media in Europe is the role of the Commission of the European Union, which has tried to define a common framework for the media industry in the member states. The central element of its politics related to media is the directive "Television Without Frontiers," first adopted in 1989, revised in 1997, and expected to be revised again in 2006. The core aim of this directive is to guarantee that a television broadcaster with a license in one member state will not be hindered in distributing the program in any other member state. Regarding children and adolescents, two other issues of the directive have become important: a common framework for advertising rules, in particular for advertising directed at children; and some basic rules aiming at youth protection in television programs. According to the statutes of the European Union, these rules have been implemented in all member states.

Despite the activities of the European Union, the media in Europe are mainly shaped by political, economic, and cultural conditions on the national level. Thus, the media environments in which children and adolescents in Europe grow up may differ quite substantially from country to country (see Hans-Bredow-Institut's *International Media Handbook* for profiles of all European media systems). Some of the differences in the most important media sectors are described next.

BROADCASTING MEDIA

Regarding radio and television, the typical European model is the dual broadcasting system; that is, a coexistence of public broadcasters on the one hand and commercial broadcasters on the other hand. Unlike the situation in the United States, public broadcasters are not just a supplement to commercial ones but a central pillar of the broadcasting system; indeed, commercial broadcasting did not take hold until the mid-1980s. Public broadcasting's charge is to provide integrative and nonprofit-oriented programming for the whole population and to reflect the diversity of opinions and social and ethnic perspectives. Throughout Europe, different models have been developed to organize this public service approach to broadcasting. The most important difference is related to the influence of the state. The United Kingdom's BBC serves as the exemplary model for many public broadcasters around the world. In other countries, such as Germany, public broadcasters are rather independent of government, and responsibility is assigned to boards or commissions that represent different societal groups. In still other countries, the state directly influences financing, strategic decisions, or the recruitment of the personal staffs of the broadcasters. This is particularly true in the former communist countries. In the course of the transformation process that started in 1989, the former state-owned monopolistic broadcasters have been transformed step by step into public broadcasters; nevertheless, the situation

today is often characterized by ongoing political influence and a lack of civil society's control of public broadcasting. Political influence on public broadcasting can also be observed in some Western democracies; for example, Prime Minister Silvio Berlusconi of Italy, who owns the biggest commercial media company in the country, has put substantial political pressure on RAI, the public service broadcaster in Italy.

As a rule, national public broadcasters offer two or three TV channels, which are targeted to different audiences. In all, audience shares for public services channels are between 30% and 50%. Children's programs, often advertising free and thus less commercialized, are integrated into the schedules of general channels. So far, thematic channels for children or adolescents are not offered by most of the public broadcasters; one exception is the German Kinderkanal (Children's Channel). Due to the ongoing process of digitalization, an increasing number of public service broadcasters are including dedicated children's channels as part of their digital offerings. However, serious financial problems currently limit public broadcasters' possibilities in this area. By early 2006, with the remarkable exception of the United Kingdom, digital distribution was far from reaching the majority of the European population.

In most European countries, commercial broadcasting did not start until the 1980s or, in the former communist countries, the early 1990s. In most countries, a few TV companies have succeeded in reaching high audience shares and generating quite a lot of advertising revenues. In general, following the respective priorities of the advertising industry, commercial channels are targeted to younger audiences; today, with very few exceptions, young people clearly prefer commercial channels to public service channels. With the increase of distribution facilities (via cable, satellite, and most recently digitalization), several global (American) commercial children's channels have become available for children in Europe, including the Cartoon Network, the Disney Channel, Nickelodeon, and Fox Kids Network.

An important condition for the availability of TV programs for children is the technical infrastructure for the distribution of TV channels. In this respect, the basic condition for watching television—a TV set at home—can be taken for granted throughout Europe; almost 100% of European households own at least one TV set (see Table 1, row 2). However, the quantity of channels available, and thus the range of children's programs to choose from, differs considerably across Europe. This is partly due to marked differences in cable policies during the 1980s and early 1990s. In 2004, the average cable penetration in Europe was 30.8% (see Table 1, row 3); however, this figure hides substantial differences. For example, in Belgium and the Netherlands, nearly the entire population has access to cable systems, whereas in Italy and in Greece cable does not play a role. Satellite, the second option for providing multichannel access, has shown a continuous growth over the past 20 years (see Table 1, row 4); in some European countries, for example, Austria and Denmark, 50% and more of the TV households receive their TV channels by satellite.

What is important regarding the program supply for children and adolescents is the difference between countries with and without multichannel environments. In countries with a high penetration of cable, satellite, or both, the majority of children have a choice between several dedicated national or international children's channels, whereas children in countries with a predominance of analogue terrestrial distribution can watch only children's programs within the respective national public or commercial channels. The latter is true for some of the Central and Eastern European countries, but also for some big Western countries, such as France (in 2004, 62% of the TV households had analogue terrestrial reception only) or Italy (around 80%) or Spain (75%). Whereas these differences between European countries have been quite stable for about 15 years, the recent process of digitalization will cause substantial changes. This process is moving especially fast in countries that do not yet have multichannel environments. The most prominent example is the United Kingdom. With a relatively weak cable infrastructure and moderate satellite distribution, until 2000 most British households were used to the few analogue channels that were broadcast terrestrially. In only a few years, digital TV (via satellite, cable, and terrestrial) succeeded in reaching more than one half of the population (in 2004, 55.8%). The distribution of digital TV is also strong in Norway (35%), Sweden and Ireland (28% each), as well as Finland (22%); besides the Nordic countries, also France (20%), Spain (19%), Austria (18%), and Germany (16%) have faced a considerable growth of digital distribution. To sum up, children and adolescents in different European countries meet quite different conditions regarding program supply. However. the general trend is in the direction of multichannel

Table 1 Audiovisual Equipment and Communication Technology in Europe, 2004

	Basis	*Total Europe*	*Western Europe**	*Central and Eastern Europe***
1) Population	in millions	788.8	397.0	391.8
2) TV households	in % of households	97.0	97.7	96.3
3) Cable	in % of TV households	30.8	33.4	27.3
4) Satellite	in % of TV households	17.4	24.6	7.9
5) Multiset	in % of TV households	41.5	52.6	30.3
6) VCR	in % of TV households	57.9	73.9	40.9
7) DVD player	in % of TV households	26.0	39.4	9.4
8) PC	in % of households	47.8	62.2	27.5
9) Internet	in % of population	38.6	52.3	22.4
10) Mobile phone	in % of population	69.8	84.8	53.8

environments and, as a consequence, a bigger number of dedicated channels for children and young people.

Another aspect of technical infrastructure is the availability of more than one TV set per household. Having more than one TV set, often with one set located in the child's bedroom, provides opportunities for children to watch without their parents. In this respect, substantial differences between Western and Central and Eastern Europe are to be observed (see Table 1, row 5). The same is true when it comes to technical equipment that enhances the television set by offering options to watch stored programs. More than 50% of the European TV households own a VCR, and more than 25% own a DVD player (see Table 1, rows 6 and 7).

NEW DIGITAL MEDIA

Over the past 10 years, the new digital media have become an integral part of the media and communication environment of children and young people. In general, this is also true for Europe. The figures provided in Table 1 (rows 8 and 9) refer to the total population; regarding children and adolescents, it must be taken into account that households with children generally have far better technical equipment than households without children. Thus, the estimates for children are substantially higher. Again, there are marked differences between countries. On the one hand, the general wealth and status of development of the respective countries seems to have an impact on availability of equipment; Table 1 shows that availability of digital equipment is substantially lower in Central and Eastern European countries. But within the group of Western countries, a difference between North and South becomes obvious as well. With regard to Internet use, Sweden (82% use the Internet) and Norway (75%) are clearly above the average, whereas Italy (35%), Spain (27%), and Greece (13%) are clearly below.

PRINT MEDIA

Another important indicator of media environments is the distribution of newspapers and other print media. Research such as that by Groeben and Hurrelmann shows that reading behavior of parents is a strong predictor for their children's reading behavior. With regard to newspaper circulation in Europe, statistics compiled by the World Association of Newspapers in the *World Press Trends* indicate that, in 2002, 10 European countries were among the 15 countries in

the world having the highest number of copies per 1,000 adults. Norway takes the first rank, with 705 newspapers distributed per 1,000 adults and a daily reach of 86%. After Japan (654 papers per 1,000 adults) come Finland (532) and Sweden (509). These data show that newspaper reading has a particularly strong tradition in the Nordic countries. Again, marked differences exist within Europe. People in Southern Europe, for example, in France (164 copies, 31% reach), Spain (127; 37%), Italy (118; 40%), and Portugal (83; 37%), read fewer newspapers than people in Northern Europe.

EUROPEAN BROADCASTING UNION (EBU)

The European Broadcasting Union (EBU, or UER for the French name, *Union Européenne de Radio-Télévision*) is a professional association of national public service broadcasters with its main seat in Geneva, Switzerland. It has 74 active members in 54 countries of Europe, North Africa, and the Middle East and 44 associate members in 25 countries from other regions of the world. The EBU was founded in February 1950 by Western European radio and television broadcasters. In 1993, after the end of the East-West conflict, it merged with the OIRT (Organization for International Radio and Television), which had been its counterpart in Central and Eastern Europe (see Zeller, 1999).

According to its website, the EBU works on behalf of its members in the European area to negotiate broadcasting rights for major sports events, to operate the Eurovision and Euroradio networks, to organize program exchanges, to stimulate and coordinate co-productions, and to provide a full range of other operational, commercial, technical, legal, and strategic services. At its office in Brussels, the EBU represents the interests of public service broadcasters vis à vis the European institutions.

Although the main focus of EBU's activities is the exchange of news and sports events (discussed following), it also facilitates co-productions between members regarding programs for children and young people. Over the years, several series have been developed, including one program from each participating broadcaster that has been adapted to other European languages and thus distributed to children throughout Europe. Television cooperation extends to educational programs, documentaries, and co-productions of animation series, and competitions for young musicians, young dancers, and screenwriters. It also includes traditional light entertainment, such as the Eurovision Song Contest; the live broadcasts from this annual event are distributed in almost all European countries and thus create a real pan-European audience.

There is also collaboration in the field of radio, covering music, news, sports, youth programs, and local and regional stations. Each year, the Euroradio network relays 2,500 concerts and operas, and the Radio Department coordinates the transmission of 440 sports fixtures and 120 major news events.

EUROVISION

The most important activity of the EBU is the Eurovision permanent network for the exchange of TV news and programs, which was created in 1954. Most news and sports pictures on European screens pass

through this network. In its first years, it was used primarily for transmissions of important events, but since 1956 it has also included systematic news exchange between the EBU members. Eurovision participants contribute items to the exchanges on a reciprocal basis, using the Eurovision network for distribution. The exchanges are organized at regularly scheduled times or as required by news developments and are managed by the Eurovision Operations staff in Geneva. The content of the Eurovision news exchanges reflects the participants' own national and international news gathering.

Today, the network manages more than 100,000 transmissions per year; around 30,000 news items are exchanged between the partners, using 50 paths on 5 satellites. The network's members reach about 350 million television viewers.

An important strategic function of the EBU is to build and maintain partnerships with international sports federations and to negotiate transmission rights for the members. Eurovision's sports acquisitions include European and world events such as, for example, the Olympic Games, the European Football Championships, the World Championships in Athletics, and the Tour de France.

EUROPEAN COMPARATIVE STUDY

Within the field of media and communications, research comparing common activities or practices in two or more countries is much advocated and increasingly conducted. Increasingly, regionalization and globalization are encouraging communication researchers to address the cross-national or transnational dimensions of cultural institutions, products, audiences, and policies. Further, funding bodies, policy imperatives, professional associations, and publication outlets in the field all increasingly favor comparative research. Yet, as the phenomena of media and communication increasingly cross borders, more researchers are taking on the challenge, asking some fascinating questions not only about the media but also about childhood, family, and culture. Although research on media use by children and adolescents has been primarily quantitative, some qualitative studies have also been conducted.

THE AIMS AND METHODS OF COMPARATIVE RESEARCH

The aims of European comparative study include improving understanding of one's own country; improving understanding of other countries; testing a theory across diverse settings; examining transnational processes across different contexts; examining the local reception of imported cultural forms; building abstract, universally applicable theory; challenging claims to universality; evaluating scope and value of certain phenomena; identifying marginalized cultural forms; improving international understanding; and learning from the policy initiatives of others. Depending on the aims, differing models for comparison are selected, each conceptualizing the similarities and differences among countries in different ways.

One key issue for comparative research is the question of country selection. In European comparisons, attempts are generally made to include Northern and Southern countries, large and small countries, and countries from diverse language groupings and religious traditions. The European Union plays a key role in developing policy relating to media and information technologies (from cultural, educational, family, and employment policy), which in turn creates a demand for policy-relevant research. Hence, countries for comparison are often selected from member states (15 in 1995, 25 since 2005). European funding sources include not only the European Commission but also the European Science Foundation (30 states) and the Council of Europe (46 states).

Comparative research faces a key issue of comparability of measures. This includes addressing differing conceptual categories and linguistic terms (e.g., *privacy, family, audience* are all terms with variable meanings across Europe). Identifying the relevant dimensions for comparison is similarly demanding.

MEDIA USE BY CHILDREN AND ADOLESCENTS

Children's time spent with media depends not only on children's media preferences in different countries and the media system in their country but also on their available time—and this will vary according to the school day, the parents' working week, conventions regarding leisure activities, shared activities, mealtimes, and bedtime. In the recent project "Children and Their Changing Media Environment," which compared 12 European countries (Belgium, Denmark, Finland, France, Germany, Israel, Italy, Spain, Sweden, Switzerland, the Netherlands, and the United Kingdom), each of these dimensions had to be compared before drawing conclusions regarding children's media time across Europe.

The only European project to compare children and young people's experiences across old and new media using qualitative and quantitative methods, "Children and Their Changing Media Environment" found similar trends in the adoption and use of a growing range of screen media (multiple televisions, video and DVD players, computers, etc.) in European homes, replicating a typology of media-rich, "traditional" (television, books, and music but no computer or Internet) and media-poor households across Europe. However, a range of differences were also found. In Dutch homes, cable television is nearly universal; computers, the Internet, and mobile technology arrived earlier in Nordic countries; Britain places the greatest stress on children's personal screen entertainment media (e.g., televisions in their bedrooms). Partly in consequence, British children watch the most television, whereas Nordic children are fairly termed "pioneers of new technologies," spending longer with interactive media as part of a more established culture of domestic and educational technology. The project also contrasted media use in "traditional family-oriented cultures" and "peer-oriented cultures." In Spain, researchers found a strongly family-oriented culture in which children spend comparatively little time watching favorite television programs alone in their bedrooms. In the United Kingdom and Germany, they found more privatized media use, partly because of cultural restrictions on children's freedom to meet friends in public locations. In the Nordic countries, demographic factors played a role in children's relatively greater freedom to determine their peer-oriented, media-rich lifestyles.

Most European comparisons address the challenges of comparison by standardizing their methodology and research tools, devoting considerable attention to equivalence and transparency in measurement procedures, and often selecting quantitative approaches to achieve this. Hence, the "SAFT" research project focused on safety, awareness, facts, and tools for children on the Internet in five European countries (Denmark, Sweden, Norway, Ireland, and Iceland). The "E-Living" project coordinated pan-European longitudinal household panels to generate quantitative data on the uptake and usage of information and communication technologies. Fewer projects attempt qualitative research, comparisons of observations, interviews, and qualitative data, being considered even more demanding, not least because of the linguistic issues. However, the "EMTEL" project took an ethnographic approach to everyday life to understand the changing place of media and technology for families in Ireland, the Netherlands, Belgium, Spain, Norway, and the United Kingdom.

In practice, cross-national research comparisons are exciting but demanding, and critical responses to cross-national research are commonplace, not least from those who conduct it. Researchers may find themselves comparing not only their findings but also their theories and concepts, methodological preferences, research ethics, writing styles, and publication strategies, all of which vary cross-nationally, over and above differences in the topic under investigation.

EXCITATION-TRANSFER THEORY

The theory of excitation transfer addresses sequential dependencies in emotional reactivity. Specifically, the theory posits a facilitation of affective and emotional reactions as a function of residual sympathetic excitation from preceding moods and emotions. In practical terms, the theory deals with two or more aroused emotional reactions that closely follow one another, and regardless of the kinds of aroused emotions involved, it predicts that the later reactions are intensified by lingering arousal from earlier reactions. The theory is thus capable of explaining, for example, why a chain of moderately distressing challenges can escalate frustration, fear, or anger to extreme levels; why people laugh especially heartily after having been frightened; why young men behave more aggressively after having been sexually aroused; why adolescents get more romantic after seeing a horror film; why children are similarly inclined to snuggle up on Mom after her reading of a scary fairytale; or, for that matter, why they become ecstatic upon learning that the terrifying wolf is dead. The theory, then, applies to emotional reactivity, whether it is evoked by exposure to media presentations or in actual situations. Moreover, its application to affective experiences during adolescence seems especially useful, as this developmental period is characterized by emotional turmoil and hyper-reactivity.

Technically speaking, excitation-transfer theory is based on the asynchrony of cognitive and excitatory adaptation to environmental stimulus changes. Neural mediation enables the quasi-instantaneous cognitive adjustment to situational changes. The systemic hormonal mediation of excitation, in contrast, is sluggish, and excitatory adjustment to change is accomplished only after considerable passage of time. The consequence of this discrepancy in adjustment time is that residues of excitation linger and influence behavior and experience for some time after cognitive adjustment to a novel situation has occurred.

As an integral part of the three-factor theory of emotion, excitation-transfer theory posits that the intensity of emotional reactivity is primarily determined by the magnitude of prevailing sympathetic excitation. To the extent, then, that residual excitation from preceding emotions is present when an emotional reaction is elicited by novel stimuli, the composite of residual and newly instigated excitation is expected to foster emotional reactivity whose intensity is greater than that specific to the new instigation alone. Residual excitation may therefore be considered to have "artificially" intensified the newly triggered emotion.

Provided that the emotions under consideration are marked by elevated sympathetic activity, the prediction of emotion facilitation entails the assumption that residual excitation from any emotion is transferable into any other emotion. Residues from fear, for example, should intensify anger, and residues from anger should likewise intensify fear. The facilitation of numerous emotions via residual excitation from taxonomically similar or discrepant preceding emotions is, in fact, well established by research demonstrations.

Although the exploration of excitation transfer has initially focused on situationally evoked emotions, the transfer facilitation of emotional reactivity has also been demonstrated for message-instigated emotions. Facilitation has been from, into, and both from and into such emotions. For example, residues from erotica-induced sexual excitation were found to facilitate subsequent situational anger and aggression; residues from disgust reactions proved capable of intensifying the enjoyment of music; and residues from exposure to rousing music fostered more laughter in response to comedy.

In examining emotionality in response to message sequences, the influence of residual excitation from decidedly aversive emotional reactions to prior segments on hedonically opposite emotional reactions of gratification, joy, and elation to subsequent segments has received most attention. For instance, it has been observed, in both fiction and reality formats, that the more intense the emotion of distressful suspense from the fear that a much-loved person might come to harm, the greater the joy upon a satisfying resolution. The facilitation of amusement in the aftermath of suspenseful or tragic occurrences, known as comic relief, is another well-established example of excitation-transfer facilitation across the hedonic divide. The

labeling of this phenomenon of mirthful overreaction is a misnomer, however, as the experience is not one of excitatory relief but, on the contrary, one of excitatory boosting of a response to comical happenings.

The application of excitation-transfer theory to emotional reactivity to message sequences is unique in that the necessary chunking and time compression of featured events invites transfer facilitation. As the presentation of emotion-eliciting events is rapidly followed by that of other events, undiminished excitatory residues can enter into and intensify reactions to the later presented events. The positioning and timing of segments in chains thus offer means of manipulation of emotional reactivity.

EXPERIENCE SAMPLING METHOD (ESM)

The experience sampling method (ESM), also known as the *ecological momentary assessment (EMA)*, is a process for gathering a substantial number of repeated observations for data analysis. ESM collects representative examples of opinions concerning aspects of daily life taken while events are taking place, allowing a respondent to give immediate and complete information and the analyst to assess information taken from phenomena at the moment they occurred. Use of this research tool, which was developed originally for psychological research, has spread to the broader social science, medical, and communications studies communities. The method is credited to Dr. Mihaly Csikszentmihalyi and grew out of his work at the University of Chicago in the early 1970s.

THE PROCESS

The basic process requires the subjects to record in a diary where they are at the moment the assessment is called for, what they are doing at that precise time, a list of their companions, if any, and what they are thinking about during the activity, as well as an appraisal of their cognitive and affective states of mind according to a variety of provided numerical scales. Seven variables are normally used to chart the relative experiential value of these activities, corresponding to these questions: (1) How intense is your current level of attention during the present activity? (2) How much do you appreciate your current activity? (3) How happy are you at this time, taking part in the current activity? (4) How intensive are your feelings toward your current activity? (5) How much do you want to be participating and engaging in your current activity? (6) How do you feel about yourself right now? (7) How important is your current activity to your plans for the future? The last question can focus on either the immediate future or the more distant future.

Recording takes place when the subject receives a signal, usually originating from either a provided beeper or the respondent's own resources (such as a watch or PDA), once every 2-hour period; full participation usually requires evaluations to take place over at least a week. The timing of the assessments is quite important and requires careful attention. As normal practice calls for reporting multiple times during the day, it is necessary to space the reports carefully to achieve a balance between random sampling and avoidance of taking two samples taken one after the other.

ESM FOR MEDIA RESEARCH PURPOSES

Researchers have found that ESM has some particular strengths that make it well suited for media-related studies, including studies focusing on younger respondents. The usual difficulties relating to faulty or insecure memory and embellished response are minimized by the reporting methods inherent in the form. The

simple, relatively short questionnaires are easy for children and adolescents to complete accurately and without confusion, decreasing the number of suspect submissions due to unfocused or mistaken responses.

The works of Mikhaly Csikszentmihalyi, Robert Kubey, and Reed Larson, in particular, are of note and utility. The detached methods inherent in ESM allow a researcher to explore the life and activities of a young adult without being viewed as an outsider during the process, which permits a more relaxed response. ESM studies have shown that many common assumptions regarding media use by adolescents have been incorrect, such as the assumption that the majority of media use by teens is a shared experience. ESM studies have shown, rather, that teens tend to spend more time alone with media sources than in groups or pairs. This finding alone calls into question many previous conclusions based on the hypothesis that adolescents tend to congregate during media use, influencing each other's choices. Another misconception that ESM studies have shown to be inaccurate is the notion that heavy television viewing accompanies adolescence in the United States and is a part of a separation from family activities. Although time spent listening to popular music increases with a subject's age, not only does television viewing decrease, but it seems to indicate a closer tie to family within a subject's life. Again, popular wisdom suggests otherwise, but a clearer picture is painted by studies in which respondents have no reason to prevaricate and are not influenced to adapt their answers to meet the expectations of a researcher.

EXTERNALIZING BEHAVIOR

Externalizing behavior, also labeled *risk behavior, undercontrolled behavior, conduct disorder,* and, more generally, *problem behavior*, can be defined as a set of two related syndromes: rule-breaking behavior and aggressive behavior. Children showing externalizing behavior are more inclined to fighting, bullying, disobedience, lying, and petty theft. When they reach adolescence, they may still be prone to fighting, rule-breaking behavior, excessive substance abuse, dangerous driving, and risky sexual behavior. Classification and analysis of such behavior are important in the study of negative consequences of media use by children and adolescents. Research on externalizing behavior has identified a number of risk factors, including certain types of media exposure.

Theoretically, externalizing behavior is contrasted with internalizing behavior, also referred to as *overcontrolled behavior* and *emotional problem behavior.* Internalizing behavior concerns syndromes such as depression, anxiety, extreme withdrawnness, and somatic complaints. Externalizing behavior may hold negative consequences for the actor, but it also affects the social environment in a direct way; other people may become victims of the sequence in which externalizing behavior is acted out. In contrast, internalizing problems first and foremost affects the mood and functioning of the person who has these problems. The distinction between these two major classifications of problem behaviors must not be made absolute, because internalizing and externalizing problems may co-occur.

CATEGORIZING EXTERNALIZING PROBLEM BEHAVIOR

Emil Kraepelin published his classification of psychiatric ailments in 1883, and ever since then, psychiatrists

and psychologists have tried to develop conceptual systems to clearly demarcate different psychiatric disorders and problem behaviors. Until the 1960s, relatively little attention was given to the systematization of pathology among children and adolescents. During the last few decades, professionals have directed their attention to the problem behavior among nonadults and have developed subsets of classification for younger age groups. Today, two types of classification systems dominate the field of taxonomy of problem behaviors. The first deals with the aggregation of knowledge of diagnosticians, systematized in the *Diagnostic and Statistical Manual of Mental Disorders (DSM).* The second typology is the result of empirical analysis of problem behavior symptoms of large clinical and nonclinical populations. The best-known example of this second type of classification is Thomas Achenbach's assessment of behavioral and emotional problems and adaptive functioning.

The *DSM* contains a clinically derived classification system developed through the consultation of diagnosticians and researchers in the field of problem behavior. They try to reach agreement on how to define and assess various disorders. This procedure has been referred to as a "top down" approach, in which experts build and refine a conceptual system that should meet wide acceptance among their peers. The most important aspect of a system such as the *DSM*'s is that it must be reliable and valid; that is, a specific type of problem behavior must be consistently and correctly qualified as such across time and situations by different professionals. The *DSM* uses a categorical approach to defining problem behavior; the border between normal and pathological behavior is relatively strict, and the same holds for the demarcation of different syndromes. Among clinicians, the *DSM* is the most widely used classification system of emotional and behavioral problems. Within the *DSM*, externalizing behavior is referred to as an *oppositional defiant disorder (ODD)*, consisting of a pattern of seriously negativistic hostile and deviant behavior, or as *conduct disorder (CD),* indicating relatively extreme aggression and antisocial behavior. Children and adolescents showing signs of ODD lose their tempers easily, frequently argue and refuse to comply with parents, annoy others and are easily annoyed, and often show signs of anger, resentment, spitefulness, and vindictiveness. Youngsters with CD may violate parental and social rules, show aggression and cruelty to people and animals, destroy property, steal, and deceive others. Children and adolescents are diagnosed with ODD or CD if several of these defining behaviors persist over a prolonged period.

The second type of taxonomy can be qualified as an empirical approach to classification. Here, classification starts from data provided by parents, teachers, or the children and adolescents themselves, by filling in questionnaires such as the Child Behavior Check List (CBCL), the Teacher Report Form (TRF) or the Youth Self Report (YSR). Through the use of statistical analysis of these data, related problem behaviors are clustered and typified as different syndromes. Thomas Achenbach and researchers inspired by his work have tried to make an inventory of behavior in the "normal" and "pathological" ranges by comparing normal and clinical groups of children and adolescents. This taxonomy is referred to as a "bottom up" approach. Naturally, this type of classification also must meet the demands of reliability and validity, but an important difference with a clinically derived system is that distinctions between the normal and the problematic are a question of degree rather than of kind. Achenbach has conceptualized the broad aforementioned internalizing and externalizing problem behavior syndromes. Although the prevalence of problem behaviors may vary between countries, there has been cross-national support for the Achenbach system of internalizing behavior (anxiety, depression, withdrawnness, and somatic complaints) and externalizing behavior (serious rule-breaking behavior and aggressive behavior). Children and adolescents who score high on scales designed to measure externalizing behavior, for example, lack guilt, have "bad" friends, steal, get into fights easily, and destroy property. Generally, they are truant from school more often or drop out of school early, and in the course of adolescence they run a higher risk of illicit drug use, risky behavior, irresponsible sex, and delinquency.

RISK FACTORS AND DEVELOPMENT OF EXTERNALIZING BEHAVIOR

Considerable research has been done on the risk factors and protective factors for externalizing behavior. Today, extensive exposure of children and adolescents to media portrayals of violence and aggression has been linked to some types of externalizing behavior. Other analysis focuses on a variety of other risk factors.

Richard Jessor's problem behavior model is one of the most systematic accounts of the risk factors and

protective factors for personal and social undesirable outcomes. Jessor believes that problem behavior originates in the genetic makeup, personality, and (perceived) environment of an individual. Such diverse factors as alcoholism and psychiatric illness in the family history, poverty, racial inequality, lack of parental support, low self-esteem, and risk-taking propensity may contribute to an adolescent lifestyle riddled with externalizing problems. Jessor's risk factor models imply that the co-occurrence of several of these factors increases the chance of later problem behavior.

Rolf Loeber and his colleagues have developed another important conceptualization of problem behavior. Loeber also catalogs a long list of factors contributing to problem behavior, locating them in the person's personality, family, peer group, school environment, and neighborhood. He assumes that three pathways to (boys') problem behavior and delinquency exist. The *overt pathway* starts with minor aggression, followed by physical fighting and then violence. The *covert pathway* consists of a developmental path from lying and petty theft through property damage to moderate-to-serious delinquency. The *authority conflict pathway* comprises stubbornness and disobedience at first, then authority avoidance as shown through truancy and running away, to full-blown, serious externalizing behavior afterward.

Although several other authors have also found that externalizing behaviors in their different childhood and adolescent manifestations are remarkably stable throughout the life course, a childhood propensity should not be viewed as an impetus for a ride on a developmental path that is narrow and necessarily single ended. For instance, fewer than half the children with oppositional tendencies, thus qualified as "hard to manage" by teachers and parent, will end up with externalizing problems in adolescence. Overall, there is a considerable decrease in aggression from childhood to adolescence, and only a small percentage of children with high childhood aggression will show continued high levels during adolescence.

THE MEDIA AND EXTERNALIZING BEHAVIOR

For more than 50 years, researchers have studied the relationship between violent content on television and aggressive behavior of youthful viewers. In recent years, increasing attention has been given to the impact of media content and usage on externalizing behavior, and current research deals not only with older media such as television and movies but also with electronic games and music videos. Scholars are also studying the role that the family may play in the context of media use by children and adolescents. For example, the Center for Research on Interactive Technology, Television, and Children is examining the possibility that violent content may moderate the relationship between family conflict and children's externalizing behavior.

THE IMPACT OF LABELING

It is important to keep in mind the distinction made by Terri Moffitt between *life-course persistent* and *adolescence-limited* antisocial behavior. Adolescence is by definition a period in which young people explore the limits of their own possibilities and the boundaries that divide the normal and the extreme, the permissible and the illegal. For many young people, breaking rules is part of the process of becoming a law-abiding citizen. They may engage in illegal activities and exhibit isolated antisocial acts. Adolescent externalizing behavior peaks around age 17 and declines rapidly thereafter. As Moffitt notes, only young people with persistent histories of externalizing problems throughout childhood and youth and into adulthood form the group of people with truly antisocial attitudes and behaviors and thus should be characterized as such.

Some researchers warn about the effects labeling may have. Classification and diagnosis may help characterize the causes of associated problem behaviors in young people; at the same time, labeling people as problematic may have effects in itself. Labels may induce stigmatization and thus deepen the problems of young people, as these labels may trigger negative expectancies in other people. Furthermore, categorization may enhance overgeneralization—that is, disregard for the specific situation and behavioral repertoire of an individual child or adolescent. Last but not least, labeling may track and pin down problems in "personal" characteristics too much and thus obscure the fact that most problems also have their origins in the interpersonal and wider social contexts in which children and adolescents function. Classification systems should be applied prudently and should work to classify externalizing problem *behaviors*, not children and adolescents as individual *people*.

FAMILY, TELEVISION PORTRAYALS OF

The public seems constantly to be concerned about the way families are depicted in television, and the past three United States administrations have each addressed this concern with strong rhetoric. The administration of George H. W. Bush is best known for this, as he advised American families to be a lot more like *The Waltons* and a lot less like *The Simpsons*. His vice president, Dan Quayle, trumped that comment when he said, "It doesn't help matters when prime time TV has Murphy Brown—a character who supposedly epitomizes today's intelligent, highly paid, professional woman—mocking the importance of a father by bearing a child alone and calling it just another 'lifestyle choice.'" Quayle's comments received so much attention that, a full decade later, CNN did a retrospective on his comments and their impact titled "Quayle: Ten Years After Murphy Brown."

Why do politicians and the public think that the way families are depicted on television is so important? Obviously, implicit in their concern is the assumption that families are presented on television differently from real life. A related assumption is that television families are presented negatively, even antisocially. A third assumption is that such depictions have sufficient socialization potential that children and adolescents are harmed by the nature of these presentations. In fact, some of the most prominent media effects theories—such as cultivation, social learning/cognitive, and other socialization theories—predict that consumption of television fare in which families are depicted as engaging in antisocial behaviors could create distorted perceptions of family life among developmentally immature viewers and could even affect children's behavior in the family environment.

DEPICTIONS OF FAMILIES IN TELEVISION

How are families really depicted on television? Is there reason for public concern because of atypical and antisocial depictions? When most people choose to address such questions, they probably cite exemplar television programs to support their theses, but doing so can lead to logical fallacies and misrepresentation. For example, the 1950s might well be referred to as the era of *The Adventures of Ozzie and Harriet,* which featured an archetypal nuclear family; however, also popular during that decade were *December Bride*, which revolved around a happy, well-adjusted widow, and *Bachelor Father*, which depicted the life of a single-parent family headed by a father. *The Osbournes*, which featured a radical, dysfunctional, real-world family, might be selected to represent the 2000s, ignoring the presence and popularity of well-adjusted nuclear families such as the one featured on *Joan of Arcadia*.

Because of the bias inherent in such asystematic selectivity, research scientists have conducted systematic content analyses to provide a more objective representation of television families over time. These investigations have included a variety of goals, including the assessment of (1) the prevalence of families on television, (2) family social class, (3) family composition and configurations over time, (4) family interactions, (5) other social realities in family depictions,

and (6) the psychological health and well-being of television's families.

Prevalence

Many early content analyses of television families focused on the prevalence of families on prime-time television and soap operas. The most general findings were that it was often difficult to tell whether or not characters had a family because relatives of most fictional television characters did not appear in the stories. However, families were well represented on television, and families of all types (e.g., nuclear, single-parent, divorced) were presented on both prime-time programming and on soap operas, even during the earliest days of television.

Social Class

Regarding family social class, content analyses have revealed that most television families were middle class. Although all social classes were represented, working-class families have tended to be underrepresented during most of television's history.

Composition and Configuration

Several scholars have examined the composition and configuration of television's families. Findings have revealed different images of the family on television, as compared with normative patterns of real family life. For example, families with children have become increasingly prominent in television programs over time (e.g., in the 1950s, 25% of television's families were childless, whereas during the 1990s only 3% of television families were childless). This pattern contrasts markedly with normative data on real families: In the 1950s, most American families included children; by the end of the 20th century, fewer than 38% of homes included children. In fact, the most typical household in the year 2000 was that of a single person with no children, which accounted for one third of all U.S. households.

Other, similar patterns of disparity between real-world families and television families have been found, including family size. The size of American families decreased rather dramatically as the 20th century progressed. In contrast, television families tended to acquire more members over time.

Other family configurations that are increasingly common in real life are rarely presented on television. One example is the so-called empty nest family, in which children are grown and living away from home. Although such families are quite common in real life and undoubtedly are normative among grandparent homes, empty nesters represent fewer than 1% of television's families.

Sometimes television does not underrepresent real-world family configurations; instead, it overrepresents them. For example, single-parent families headed by fathers are relatively rare, according to census data, ranging from 1% to 3% of households between 1950 and the present. Yet, such families have been consistently prominent on television, ranging from 17% in the 1950s to 23% to 25% in more recent decades. In some racial and ethnic groups in America, families with fathers in their households are relatively rare.

Family Interactions

In terms of family interactions, research has found that husbands and wives were relatively equal in initiating interactions and that most conflict occurred in husband–wife dyads. Parents were most likely to interact with same-sex children, and affirming interactions outnumbered disaffirming interactions by a substantial margin. Taken as a whole, the majority of family interactions have been found to reinforce the traditional view of family relations, with males dominating and females nurturing, although many exceptions to that pattern have been noted. Among African American families, husbands and sons have been found to be more active in interactions than mothers and daughters.

Other Social Realities

Other investigations have systematically examined other social realities in family depictions. Early studies showed that wives and mothers were typically concerned with cooking, cleaning, and children and delegated most authority and responsibility to male characters. For the most part, work and family were presented in separate spheres in television's early family shows, and when a wife or mother was shown having work responsibilities, she often had problems with her personal relationships. In later programs, the image of "Supermom" became common, with the working wife and mother presented as doing all things well.

Some research has been conducted on the depiction of families of color on television. The typical conclusion has been that the social realities of African American, Latina/o, Asian American, and Native American families have not been portrayed accurately. In fact, the typical conclusion has been that portrayals of families of color are based on stereotypical, stylized views of a small number of decision makers in the television industry.

Psychological Health

Other research has asked more penetrating questions, such as "How psychologically healthy are America's television families?" Questions assessing the psychological health and well-being of television families may well get more directly to issues of prominence of antisocial depictions. To date, research that has systematically examined the psychological well-being of television families has determined that the vast majority of families were psychologically healthy, whether the criteria of comparison were taken from family therapy or from psychiatry. Only 2% to 4% of families suffered from poor communication practices, lack of cohesion, or lack of ability to manage change within the family environment. Given these data, if the mental health of television's families were compared to the psychological profiles of normative real families, undoubtedly the typical television family has been much more healthy psychologically than the typical real family.

FUTURE RESEARCH

An obvious next step in investigations of family depictions on television is to more systematically compare the families of television with those of the real world. Even more sorely needed are studies examining the impact of viewing television's atypical family configurations, interactions, social conventions, and mental health on the social reality of child and adolescent viewers.

FAMILY COMMUNICATION PATTERNS MODEL

A variety of studies suggest that family communication norms can help explain media-specific discussions and effects. The family communication patterns (FCP) model, developed by Jack McLeod and Steve Chaffee, has provided one valuable way to look at the effect of the family communication environment on children's attitudes and behaviors. It has been especially important for scholars studying routes to parental influence on media effects.

The model addresses the gap left by the unfortunate fact that many parents do little intentionally to affect the media's influence on their children, perhaps not realizing how influential they can be. They may be especially unaware of how important they are as an indirect influence. According to McLeod and Chaffee, parents teach children how to manage and interpret information in general through their own family communication patterns. This, then, affects the way children approach and internalize media messages.

The FCP model conceptualizes parent-child communication as taking place along two relatively independent dimensions. The first, called *socio orientation*, reflects the parent's desire for harmonious interpersonal relationships in the family through the emphasis of conformity and control. The second dimension, called *concept orientation*, reflects the parent's emphasis on sharing and challenging ideas. Some scholars have suggested that socio orientation reflects a desire to maintain the status quo and is internally focused. Concept orientation reflects a more external focus. Parents can emphasize one dimension, both dimensions, or neither.

When McLeod and Chaffee conceptualized two dimensions of communication style, it represented an

important parsing of the prevailing unidimensional views of parenting style, such as those of Diana Baumrind, Brant Burleson, and others, which combined behavior management orientations with communication characteristics. McLeod and Chaffee's typology attempts to explain the importance of considering management style and communication style separately. This has made the FCP model particularly useful for the study of media-related parenting strategies, such as rule making and discussion of content.

In the FCP model, parents low on both socio and concept orientation are called *laissez faire* because they do not emphasize any orientation. Parents high on socio orientation but low on concept orientation are considered *protective* because they emphasize control and shy away from the discussion of ideas. Parents with the opposite orientation—low on socio orientation and high on concept orientation—are called *pluralistic* because they welcome ideas and de-emphasize conformity. Ironically, some research has indicated that children of pluralistic parents tend to model their parents more than do children of protective parents. Finally, parents emphasizing both orientations are known as *consensual* because they think open discussion is important but nonetheless want to maintain family harmony and control.

The model was designed from the parent's perspective rather than the child's, inspiring debate among scholars regarding the extent to which the message parents think they send is the message children receive. A variety of studies have found that parents' reports correlate only modestly with children's reports. Some have found that children's reports provide better predictive validity, whereas others have suggested that the constructs are too abstract for preadolescent children to appraise. Other research suggests that children can respond to the questions but interpret them differently from adults.

To measure socio orientation, sometimes called *control orientation*, parents traditionally indicate how often they tell their children that their ideas are correct and that children shouldn't question them, how often they answer their child's arguments by saying something like, "You'll know better when you grow up," how often they say that we should give in during arguments rather than make people angry, how often they say that children should not argue with adults, and how often they say that some things just shouldn't be talked about. To measure concept orientation, sometimes called *communication orientation*, parents traditionally are asked how often they tell their children that people should look at both sides of an issue, how often they tell their children that every member of the family should have some say in family decisions, how often they tell their children that it's important to question other people's opinions, how often they tell their children that kids know more than adults about some things, and how often they tell their children that it's important to get their ideas across even if others don't like it. The questions frequently are modified so that children can be asked their perceptions of their parents' behavior.

The FCP model continues to attract attention because it has been found to predict a variety of socialization outcomes relevant to media use, parental mediation, public affairs, health decisions, academic achievement, persuasion, and consumer attitudes. For example, children from socio-oriented families tend to watch more entertainment television, including televised violence, but without much discussion. They tend to use television as a facilitator for social interaction and are more responsive to persuasive appeals based on the social status of the messenger. Children from concept-oriented families tend to watch more public affairs programming, to know more about public affairs, to be more involved in civic activities, to be more skeptical of advertising, to be less likely to identify with violent characters, and to have parents who practice active mediation. They tend to evaluate persuasive appeals on the basis of argument quality. With regard to the full typology, scholars have found that children from protective families are easily influenced by authority figures and that children from laissez faire families tend to be influenced by peers and a variety of other sources. Children from consensual families tend to reject messages that conflict with their parents' viewpoints, whereas children from pluralistic families are more autonomous.

The model also continues to hold the interest of scholars trying to achieve a better understanding of the model's significance and validity. Some choose to employ the *revised family communication patterns model (RFCP),* reconceptualized by L. D. Ritchie as comprising *conformity* and *conversation* orientations, whereas other scholars prefer to use the original measures.

FAMILY ENVIRONMENT, MEDIA EFFECTS ON

Two noticeable evolutions in research on media effects on the family environment are (a) a shift from a television perspective to an emphasis on the changing media environment and (b) a shift from a child-centered approach to a family approach.

The first evolution is a very slow one that sheds light on a problematic issue in effects research. From the day of its introduction in the family home, television has been regarded as the central medium. Until the 1980s, the main body of research concentrated on the effects of television on family life and especially on the role of parents as mediators of television content for their children. As a result, the family was conceptualized as the context for television viewing. With the introduction of the VCR in the 1980s and the personal home computer in the 1990s, the focus on television was expanded to include these new media. However, this change in perspective only shifted attention from one media appliance to another without recognizing the importance of the entire media environment.

Furthermore, emphasis has often been placed on displacement hypotheses, with researchers studying how new media affect television viewing and whether time spent with new media displaces time spend with older media. Early research into the effects of the Internet on the family environment, for example, indicates that time spent on the Internet displaces time spent in social activities. The more time people spend on the Internet, the more they lose contact with their social environments. This effect is most apparent in people who are heavy users of the Internet. Use of the Internet could lead to privatization (retreat into the family home) and individualization (retreat from family life). However, the Internet is in itself a social medium. It is used primarily to communicate with others through activities such as chat, email, virtual communities, and blogging, which are especially popular with teenagers. Communication through the Internet gives them private spaces that cannot be invaded by their parents. Phone conversations can be overheard by parents, but chatting on the Internet makes private conversations possible.

FAMILY RELATIONSHIPS AND THE MEDIA ENVIRONMENT

Previously, the family environment was regarded as a given, and the individual family member was studied apart from his or her surroundings. Today, analogue reasoning is found in relation to the family's media context. Researchers now argue that the use and presence of a media appliance cannot be studied separately from the use and presence of other media appliances in the home. Furthermore, when media appliances enter the family environment, they are brought into a changing network of family relationships and media uses. Families are becoming centers of multimedia activities, and children's bedrooms are evolving into multimedia islands. As a result, the implications of these new media for family life have emerged as a focus of recent research. Researchers ask whether new media cause changes in family relationships and how the

"I'm too tired to listen to a story tonight, mom. Just e-mail something and I'll read it tomorrow."

network of family relationships incorporates new media. Therefore, it is not a question of how these new media affect family life or what families do with these new technologies. Rather, it has become a question of how they are incorporated into family life and what importance families attach to them. Increasingly, these questions are being addressed using qualitative research techniques. It is clear that families cannot be seen as black boxes in which media are consumed according to the intentions of a computer designer. Instead, families incorporate media into their everyday lives. In this respect, media use is not mediated by a family context but embedded in family dynamics; as such, it has implications for family life. It is a reflection of general family functioning.

When a new media appliance enters the family home, it is used very intensively. This can create an imbalance in family relationships. For example, when the sole Internet connection is in a living room where family members previously did not come together, conflicts are created. Family members who previously spent much time alone in the home are forced together in one space, whereas previously they spent more time alone. In reaction to this imbalance, families may look for solutions that enable them to return to their former patterns of family life. For example, they may decide to have an Internet connection in every bedroom so that family life can get "back to normal."

Another important effect of media in the family environment is the creation of new expert roles. Especially with the introduction of the PC and the Internet, young people often are regarded as the experts. In most families, they are more knowledgeable about new media. They know how to use new media and are more flexible in their use. This gives them a new position in the family environment that sometimes ameliorates problems in relationships between generations. For example, a father and his son may go to the same computer club and share an interest in computer software. Siblings who are hooked on computer games may play together and exchange cheat codes.

Although parents and siblings influence children in the family environment, family members are also influenced by their peers. Children are sometimes "forced" to watch certain television programs in order to keep up with their friends. They may need to follow up on the latest computer games or certain Internet sites in order to be "cool" and to be accepted by peers. This peer pressure may cause problems for family functioning when, for example, parents do not want children to connect to the Internet or forbid children to play certain computer games. Parents, too, can be under peer pressure. For example, they can be pressured by colleagues to have email at home or to do electronic banking. Thus, peer pressure about media can affect the family environment.

FAMILY RELATIONSHIPS, TELEVISION AND

Opinion regarding the family on television is divided. For the most part, scholars have concluded that contemporary television families are little different from their 1950s counterparts. According to this position, television family relationships remain characterized by mutual affection, involvement, and concern; family life continues to be played out in explicit ease and comfort, reflecting an established ideology of achievement and success. In contrast, critics argue that, not only have family relationships become highly conflictual, but contemporary parents, especially fathers, lack both authority and good sense, and modern children are undisciplined and disrespectful.

Because almost all discussion of television families has focused on those depicted in domestic comedy, it is unlikely that opinion is divided as a function of program type. Indeed, observers disagree even when discussing the same family. It is more likely that beliefs about the family on television are systematically influenced by researchers' points of view. Specifically, content analyses appear to encourage the conclusion that, with rare exception, television family life and relations are warm, respectful, and orderly. Attributional analyses, meanwhile, center on the sense that viewers make of television content and offer considerable evidence of decline in the television family experience, especially that of television children.

MAKING SENSE OF THE TELEVISION FAMILY: A VIEW FROM THE SCREEN

Content analyses suggest that television promotes a traditional family model, in which males behave in instrumental ways and assume the role of primary provider and females behave in expressive ways and assume the roles of nurturer and caregiver. Indeed, even nontraditional families appear to subscribe to conventional family values.

Consistent with this family model, males exhibit behaviors often associated with relational power. For example, compared to wives and mothers, husbands and fathers are more talkative, more likely to act unilaterally, more likely to blame, and more likely to seek compliance from other family members. Likewise, in sibling relations females are less likely than males to use commands and more likely to seek information, to show affection, and to provide reassurance. In both adult and child relations, males are more likely than their female counterparts to use reasoning during conflict. Finally, parent-child relations are seen to be mutually satisfying in that children are compliant and seek parental attention, whereas parents behave in complementary ways, providing discipline, support, and affection.

In sum, content analysis often suggests that television life is based on a traditional model in which rights and responsibilities are divided on the basis of gender. Perhaps because spousal, parent-child, and sibling relations are noncompetitive, conflict is seen to be comparatively rare and easily resolved. In a larger sense, family relations are judged to be affectionate, involving, and mutually fulfilling. There are only two potential violations of this model: the nature of working-class families and the status of contemporary fathers.

Working-class families are distinguished by a gender inversion. More specifically, working-class males are portrayed as inept, immature, stupid, lacking in good sense, and emotional, and they are increasingly the butts of jokes, especially those told by mothers. Across time, they have become more likely to be judged foolish. At the same time, working-class wives are more likely to be portrayed as relatively intelligent, rational, and responsible. However, although this may not conform to the "Tarzan–Jane" ideology apparent in middle-class television families, working-class families are more cohesive, more helpful, and both friendlier and happier than middle-class families, suggesting that the general effectiveness of the traditional family model is unaffected.

MAKING SENSE OF THE TELEVISION FAMILY: A VIEW FROM THE ARMCHAIR

Attributional analyses (i.e., those based on viewers' interpretation of television content) have suggested that spousal relations have become more egalitarian across time so that, in modern families, spousal rights and responsibilities are more often shared than divided on the basis of gender. In addition, although contemporary spouses were seen as more argumentative, they were also judged more explicitly affectionate and more sexually intimate, implying that spousal relations have become more emotionally expressive and not simply more conflictual. Like earlier spouses, modern couples were defined as mutually involved, trusting, able to manage the routine of day-to-day life, happy, and likely to remain together. Notably, this model of contentment and stability did not generalize to working-class spousal relations, which were seen as comparatively closed, highly conflictual, and unsatisfying.

Attributional analyses found that the evolutionary trajectory of parent-child relations was more ambiguous. Parents and children were seen to have become more involved with each other, more trusting, friendlier, and better able to manage daily life. At the same time, these relationships were rated as more argumentative than in earlier families, and modern parents were judged less able to socialize children effectively.

In contrast to other family relationships, those among siblings were judged to have become significantly distressed over time. Viewers rated contemporary siblings as less trusting, less friendly, more hostile, less able to manage conflict, and less able to socialize each other appropriately. Modern siblings were also seen as less happy together and less likely to remain close in the future than their earlier counterparts.

CONCLUSIONS

The status of the family on television is uncertain. Extant research suggests quite opposite conclusions that appear to depend on perspective. Nonetheless, the meaning and attributional significance of television interaction are determined by the viewer, suggesting that content analysis may yield little insight into viewers' understanding of the television family experience. At the same time, Bryant, Aust, Bryant, and Venugopalan (2001) used established diagnostic criteria to evaluate television family interaction and reported that all families and all individuals were defined as healthy, raising the possibility that the perceptions of distress apparent in attributional analyses may have no clinical basis.

FAN CULTURES

A fan culture forms when a group of fans organizes around their shared interest in a media text or personality. The best-known, most visible examples of these cultures include Star Trek fans, Elvis impersonators, and "Dead Heads," or Grateful Dead fans. However, fan cultures exist for an extensive variety of television programs, films, books, comic books, actors, and musicians. Among young people, one can find fan cultures for everything from *Harry Potter* to *The OC.*

Like any culture, organized fan communities operate within a set of norms and rules of behavior. Frequently, behaviors that are acceptable within the fan culture carry a different meaning for the outside observer. For instance, the culture at large may view as aberrant dressing up like a favorite character for a

Young Harry Potter fans, dressed as witches, await the arrival of author J. K. Rowling before a reading of her fifth book in the series, *Harry Potter and the Order of the Phoenix,* at the Royal Albert Hall in London. Some 4,000 schoolchildren gathered on June 26, 2003, to hear Rowling read from the book five days after it was launched around the world. On the first day, it sold 5 million copies in the United States, breaking sales records previously set by *Harry Potter and the Goblet of Fire.* That record was broken in July 2005 by *Harry Potter and the Half-Blood Prince,* which had first-day sales of 6.9 million in the United States.

film premiere or fan convention. Within the fan community, however, this costume wearing makes sense as one of the many activities in which fans engage as they enjoy and pay homage to what they love.

STUDIES OF FAN CULTURES

To understand fan cultures, researchers often employ the ethnographic approaches used by anthropologists in the field, including interviews with and observation of members of the culture. In a study of young women fans of *Beverly Hills, 90210,* for instance, E. Graham McKinley watched episodes with groups of fans, observed how they talked to each other about the show, and then interviewed the girls.

Whereas this and other studies have examined fans' talk about the object of their fandom, another area of interest in the study of fan cultures is the role of fans as cultural producers. For example, one study has looked at websites created by girls devoted to teen heartthrob Chad Michael Murray, and another has examined websites created by fans of female-oriented, or *shoujo,* anime (Japanese animated series like *Pokémon* that have become very popular in the United States). Drawing on studies of mostly adult fan cultures, these studies of girls' fan cultures share an interest in fans as active audience members who interpret and use texts in their lives.

In what is considered a seminal work in fan culture research, Henry Jenkins found that fans rework or "poach" the original text to suit their own needs through fan fiction writings—original stories written by fans using a show's characters and universe. Jenkins found themes of resistance to dominant cultural ideologies in these fan works. Other studies, however, including those examining girls' fan cultures, have not found these same themes of resistance. Rather, they have found that these fans focus on the things that typically interest girls: boys, romance, and relationships. This lack of resistance to a "male-oriented" culture does not mean that these girls are not actively using the texts. In fact, these studies find that the girls negotiate their identities within their fan cultures and that they are very active as both interpreters and producers of content.

FAN ACTIVITIES

Prior to widespread use of the Internet, an individual had to join a local, regional, or even national fan club to participate in a fan culture. In addition to local meetings and national conventions, fans communicated with each other through fanzines, independently produced fan magazines distributed through mailing lists. Today, thousands of fanzines exist, and fan conventions are more popular than ever. At the same time, the Web offers fans around the world the ability to instantly connect with and talk to one another 24 hours a day.

The most fundamental activity in which fans engage is talking about the show, personality, group, or text that they love. Fans get together for analysis and debate, most often through website message boards and chat rooms. In the process, they form communities and develop friendships that often extend beyond the world of the fandom that brought them together.

In addition to talking with each other, fans produce and perform for each other. Fanzines are just one example of the materials fans produce and share. Technology has given fans the opportunity to express their creativity in a wide variety of ways. Fans create their own websites; write, read, and critique fan fiction, poetry, and fan songs, known as *filk*; and create fan art and even mini-videos (usually clips from a show set to popular music).

Other activities of fan cultures have also been facilitated by technology. Fans typically spend time acquiring knowledge about the object of their fandom. This knowledge may include everything from episode titles and numbers to background information on the actors, the writers, and anyone else involved in the production. The wealth of information available on the Web makes this data gathering and sharing easier.

Not all fans engage in all of these activities. In fact, most fans probably engage in very few of the activities described here. Researchers have attempted to describe what distinguishes a fan from other audience members based on the level of involvement. Yet, there is another way to look at this issue. In an overview of definitions of fans, Matt Hills points out the importance of the act of identifying oneself as a fan, something that may be particularly important for young people. Youth culture is stratified by genres of music; that is, young people identify one another as belonging to certain groups based on what types of music they like. Teens who are fans of heavy metal typically do not hang out with those who are into hip hop. Thus, identifying oneself as a fan of something may be the most fundamental fan activity.

YOUTH FANS AS CONSUMERS

Thanks to such technologies as the Web as well as the growth of popular media, fan cultures are no longer on the fringes of society. It is easier for fans to participate, and fan cultures are much more visible. At the same time, fans are also more visible to the producers of popular media. Most of the research on fan cultures views fans as active interpreters and producers of content; however, Matt Hills argues that it is important to recognize that fandom is also an act of consumption. This may become especially true as youth media producers recognize the power of the youth audience and the desirability of creating loyal fans for their products.

The official website for one popular teen drama, *Dawson's Creek,* exemplifies the changing climate for youth fans. The show's production company, Sony Pictures Entertainment, courted fans through an elaborate website (www.dawsonscreek.com) that offered fans a ready-made, professionally produced fan community. The multilayered site gave fans the chance to connect and share fan fiction via message boards. It included extensive background information on the characters as well as the actors, the writers, and the creators of the show; it allowed fans to communicate with a member of the production staff; and it included "extra-textual" material related to the show, such as "secret scenes" that were cut from episodes before they aired.

The foregoing list covers only a portion of the content available on the website. The most important aspects of this site for fan cultures is that it provided fans with the types of materials they might have created and sought out on their own, moving them away from their roles as active producers and into those of passive consumers.

FANTASY, MEDIA EFFECTS ON

Fantasy is a powerful psychological process that enables human beings to create new ideas and concepts in their minds by building on existing ones. Questions and conjecture about fantasy and its significance for individuals, societies, and cultures have elicited scholarly and public debate throughout history. The question of whether various media, particularly television, have an impact—either positive or negative—on children's creativity, imagination, and play has been the focus of various studies throughout the years. An overview of the research on media effects in this area suggests that the overall negative effects of media on children's creativity, imagination, and fantasy play are stronger than its positive effects. Reception studies of fantasy offer an alternative to media effects research on this topic and suggest ways in which children can creatively use media elements.

Although the range of information available through communication technology and various

media has expanded recently, specific concerns about children and the development of their capabilities for imagination have remained very much the same. The claim that enjoying leisure media, and television viewing in particular, is a passive experience for children—one that suppresses both cognition and imagination—has been a common thread in the public debate. From this perspective, the child viewer is but a passive receptacle; the visual nature of media such as television, video and computer games, and the Internet, is thought to rob children of the opportunity to form images in their own minds as they do when reading books. At the same time, any casual observer of children's everyday lives can attest that media content is deeply integrated in children's imaginations and fantasy play.

CREATIVITY AND IMAGINATION

Several early correlation studies as well as experimental ones found negative relationships between television viewing and children's scores on a variety of creative tasks, such as thinking, problem solving, and writing. Several studies compared children's performance on a variety of tasks before and after the introduction of television into their lives. Although individual studies may be challenged on conceptual or methodological grounds, the accumulative picture coincides with the popular belief that heavy television use, particularly violent television, impedes the development of children's creative abilities.

Several researchers investigated how various media differ as stimuli of creativity and imagination. One area of research focused on whether a televised version of a story stimulates more or fewer creative ideas, story lines, and problem-solving solutions than the same story told verbally (in audio or print forms). These studies confirmed the hypothesis that processes of imagination (operationalized as any form of representational activity that creates new entities such as characters or events) were better stimulated by radio than by television. One explanation offered is that that the *visual superiority effect* of television is confounded in regard to comprehension by the advantages of the auditory–verbal track.

FANTASY PLAY

Studies of the role of television as a stimulant of fantasy play have examined the hypothesis that television viewing may displace free fantasy play (interchangeably termed *pretend, make-believe, or imaginative* play) in young children. Engaging in creative imaginative play is presumed to be essential for children's development and is one of the most important ways in which they learn about their environments. Accumulated research suggests that, ultimately, the types of content children watch are more important in determining outcomes of fantasy and imaginative play than the quantity of time spent viewing. One related finding is that fantasy violence in television content may inhibit or take the place of imaginative play, whereas certain educational, prosocial programming may actually encourage it. For example, viewers of programs oriented toward prosocial behaviors, such as cooperation, expression of empathy, delay of gratifications, ability to express feelings, and the like, have been found to incorporate such behaviors in their play. Several researchers also argue that it makes little sense to deliberate whether one kind of imaginative play induced by television (e.g., playing "school" or a particular profession) is of higher quality and more desirable than another (e.g., playing "war of the good against the evil").

DAYDREAMING

Several researchers have suggested that television's visually concrete presentational forms inhibit children's daydreaming, in comparison to the abstract nature of words in print or spoken language. They assume that the ready-made fantasy world of television does not require significant mental effort and that the fast pace of the programs does not leave room for daydreaming while watching. A competing hypothesis is that television may stimulate program-bound daydreaming; in this view, the daydreaming of heavy viewers of violence, for example, will be preoccupied with aggressive themes and superheroes closely related to their favorite television narratives. No studies have dealt with this area, so there is no evidence to support or deny these competing hypotheses.

RECEPTION STUDIES OF FANTASY

The preceding work on the nature of the relationship between mediated texts and children's fantasy worlds is rooted in the research tradition of media effects. Alternatively, reception studies based on interviews of children along with examination of their stories,

drawings, and other artwork have applied a different research approach that enables children to give voice to their experiences and meanings as they are embedded in their everyday experiences at home, in school, and with friends. One such cross-cultural study demonstrated the centrality of diverse media in children's fantasies. The degree of integration of media material ranged from the very "thick," which included adoption of settings, characters, and plot lines taken from media texts (such as a setting from a Disney movie, Pokémon characters, or a plot line of a cartoon), to "thin" traces, in which a media reference was found to be of peripheral importance to the overall nature of the child's fantasy (such as an adoption of a Superman cape or a television character's name). Further, in fantasizing, children mix and match media elements in ways that facilitate their own fantasy worlds and allow them to best experience their wishes to act in these worlds. They highlight and expand on those aspects of the original media worlds that are particularly attractive to them and adapt or erase those that hinder or are not relevant to the wished-for experience. One might say they play the role of editor as they formulate their own stories, using original elements of their own creation and drawing from mediated materials as needed for the finished product.

FANTASY–REALITY DISTINCTION

A central concern in the research on children's cognitive development, one that can be traced as far back as Jean Piaget's research, has to do with how children understand the world around them. A key dimension of that understanding is the extent to which children distinguish between fantasy and reality. Both Sigmund Freud and Piaget were concerned with children's ability to distinguish between what was real and what wasn't among thoughts and behaviors that were self-generated. It wasn't until the 1970s that researchers turned systematic attention to studying the extent to which children actually used the categories of "reality" and "fantasy" to make sense of the world around them. The results of several studies around this time showed that the use of these categories increased steadily with age but that even sixth graders did not make the same sorts of distinctions between fantasy and reality that were typical of adults. Although media were not the primary focus of some of this early research, the studies did use pictures of fantasy media characters (i.e., Donald Duck, Big Bird, and Snoopy) in some of the categorization tasks, and their study certainly fueled subsequent research on the importance of the fantasy–reality distinction for children's understanding of media messages.

THE CONCEPT OF FANTASY VERSUS REALITY

In 1977, Robert Hawkins published an influential article that summarized some of the supposed effects of television content that varied as a function of children's perceptions of the reality of that content. However, in his review of this literature, Hawkins noted that measures of perceived reality varied widely and that this fact gave rise to a question about the nature of the concept itself. The remainder of his article was devoted to the conceptual and empirical nature of judgments about the reality of television content and introduced notions that became seminal in the literature. Hawkins introduced four different dimensions that might capture how children conceive the notion of television reality. The first dimension includes a continuum that ranges from perceptions of television content as a "magic window" of reality (where television is simply a separate window in which everything is just as real as events that happen

anywhere else) to perceptions of television content as purely dramatic depictions. A second dimension deals with expectations about life and includes judgments on a continuum that ranges from television events matching social expectations about the world or failing to match those expectations. A third dimension, specificity, involves the possibility that children's perceptions about reality might differ depending upon the level of specificity of the questions that they are asked about television content. Finally, a fourth dimension involves the possibility that children's perceptions of reality might vary depending upon whether those perceptions are about television characters, events, or the usefulness of those characters and events for everyday life. Hawkins gathered some empirical support for these dimensions and made it clear that there were developmental differences in perceptions of television's reality on these dimensions.

Building upon Hawkins' research, John Flavell and his colleagues studied how 3- and 4-year-olds interpreted various television images. They found that 4-year-olds tend to distinguish between real objects and televised depictions of those objects. However, 3-year-olds showed a tendency to perceive televised depictions as real, physical objects. For example, they tended to believe that the juice would come out of a glass that was shown on television if the television set itself were turned upside down. The researchers noted that this sort of judgment error was not confined to televised images but extended to simple two-dimensional photographs. They proposed a four-step developmental sequence to describe how children gradually learn to distinguish between television content that is real or realistic and that which is not.

Daniel Chandler provided a comprehensive overview of the different ways in which scholars following Hawkins have conceptualized and studied the fantasy–reality distinction. One important aspect of the distinction involves *physical actuality*, or the judgment about whether a person or event depicted on television is thought to exist in the real world. This criterion is commonly used by 7-to-8-year-old children as a basis for distinguishing between reality and fantasy. The *possibility* criterion is also often used by children in making the fantasy–reality assessment of media content. Research by Patricia Morison and her colleagues revealed that use of this criterion followed a developmental course, with 5-to-6-year-olds using it less than one fifth of the time to justify their fantasy–reality judgments, 7-to-9-year-olds using it about one third of the time, and 11-to-12-year-olds using it nearly half the time.

PRACTICAL IMPLICATIONS

Probably the most important practical line of research to develop around children's perceptions of fantasy and reality of media depictions was initiated by Joanne Cantor and her colleagues. Cantor assumed that children's emotional reactions to potentially frightening media depictions were closely connected to their cognitive perceptions, judgments, and interpretations of the characters and events featured in those depictions. This assumption is well grounded in cognitive psychology. In writing about the nature of emotion, Nico Frijda described the *law of apparent reality* by observing that, to the extent that people think about events as real, they tend to experience a more intense emotional reaction to those events. Cantor's studies, guided initially by Piaget's developmental theory, have focused on documenting the nature of developmental differences in children's perceptions of the reality of media depictions and using those differences to predict and understand the presence and intensity of fright reactions that children experience as a consequence of media exposure.

One practical finding to emerge from Cantor's studies is that young children, particularly in the preschool years, tend to perceive as real many of the characters and events that older children perceive as belonging to the world of fantasy. Consequently, whereas older children are more likely to experience fright at media depictions that show real threats and possible harms from real-world events, younger children tend to experience fear of a whole class of characters (e.g., the Incredible Hulk and wicked witches) and events (e.g., visual transformations) that older children and adults regard as pure fantasy and consequently quite harmless.

Future research on the fantasy–reality distinction promises to include more studies that seek to understand the nuances of children's perceptions of media content. In addition, research on individual differences may reveal that adolescents and adults differ according to the level of perceived reality ascribed to media content and consequently in the ways in which they experience the effects of exposure to that content.

FATHERS, MEDIA PORTRAYALS OF

Since the inception of television, programs and commercials have dramatized the family, delivering the trials and joys of domestic life to the living rooms of viewers often watching in the company of family members of their own. It is interesting to isolate for close scrutiny the depiction of one particular family member, the television father. From Ward Cleaver to Mike Brady and from Bill Cosby to Homer Simpson, the television father has been known to take on the status of cultural icon. Sometimes viewed as the "head of the household," his portrayal seems especially central to the family as a whole.

Slow shifts have taken place in society at large, in which the division of parenting and housework responsibilities between women and men has begun to be slightly more balanced. Portrayals of the television father can reveal much about gender roles and cultural norms. To some extent, media portrayals of men's family roles reflect increases in household responsibilities shouldered by real-life fathers and husbands, but gender stereotypes remain.

THE SITCOM FATHER

The contemporary sitcom father often seems to struggle with his role as a parent and husband. Humor is furnished through his missteps, occasionally met with derision from other characters. Frequently short tempered and short of common sense, sage advice, or tact, the recent sitcom father has been described as a buffoon. Of course, conflict and shortcomings are the stuff of situation comedies. Yet, when considering how portrayals have changed over the years, a case can be made that fathers have gone from "knowing best" to knowing little.

Changes Over Time

The proportion of humorous interactions occurring at the expense of the father increased from the 1950s through the 1990s, according to a content analysis conducted by Erica Scharrer. The recent sitcom father is on the receiving end of humor (i.e., being made fun of) more often than in decades past. There is additional evidence that the sitcom mother has wrested the comedic upper hand from the father. In sitcoms airing in the 1950s, jokes told by the father at the expense of the mother outpaced the reverse by 3:1. In the 1990s, the mother was making fun of the father at a rate better than 2:1. There was also a consistent trend over time toward sitcom fathers who could be characterized as foolish, unintelligent, or inept. Thus, contemporary sitcom dads (like Ray Romano's character on *Everybody Loves Raymond*, Peter Griffin on *Family Guy*, or Hank Hill on *King of the Hill*) tend to be portrayed as less successful than sitcom fathers of the past (like Ward Cleaver of *Leave It to Beaver* or Mr. Cunningham of *Happy Days*).

Blue-Collar Dads

The social class of the sitcom family also appears to make a difference in how the father is depicted. Muriel Cantor has argued that domestic comedies featuring

working-class families (*The Honeymooners, All in the Family, Roseanne*) present the father figure as more foolish than comedies featuring middle- or upper-class families (*Leave It to Beaver, Father Knows Best, The Cosby Show*). Richard Butsch has observed that the working-class family man on sitcoms can best be described as a buffoon whose stupidity is a frequent source of laughter. In Scharrer's study, the socioeconomic status of the family helped to dictate the level of foolishness of the portrayal of the sitcom father. Her content analysis shows nearly twice as many jokes told at the expense of the father in working-class families, as compared to upper-class families.

FATHERS IN COMMERCIALS

Progress has been made in terms of the number of males depicted in commercials as parents or as performing household chores. Yet, men remain more likely to be shown employed outside the home, whereas women are more likely to be shown working within the home in roles as spouses or parents. Gayle Kaufman's content analysis of men's family roles in commercials reveals a number of further persisting inequities. Father and husband characters do just one quarter of all of the cooking shown and an estimated 20% of the housework and grocery shopping. Whereas father characters are seen playing with their children more than mothers are, care-providing activities (such as giving medicine to or feeding children) are performed twice as often by mothers than by fathers.

Kaufman observes that, when father characters perform household chores such as cooking or caring for children, they frequently have difficulty with these tasks. Examples of such commercial depictions include fathers sending children out in summer clothes during winter weather, or ordering takeout when mothers are not around because they are unable to cook. This tendency was further evident in an additional study of prime-time television commercials in which the failures of fathers and husbands at domestic chores (much more common than the corresponding failures of mothers and wives) were frequently presented as sources of humor.

CONCLUSION

Not just in situation comedies and television commercials, but also in other television genres and additional media forms, the depiction of the father these days seems to be one of a bumbling buffoon. Movie plots, for instance, often involve fathers who are faced with sudden, sole responsibility for child care and housework but lack the necessary skills (e.g., *Mr. Mom, Three Men and a Baby,* or *Big Daddy*). However, despite the foolish tendencies of modern and working-class sitcom fathers, they often ultimately succeed. Their paths to parenting decisions are often plagued with problems, but typically a positive resolution prevails, and their love for their wives and children is apparent. Clearly, portrayals of fathers in the media are complex and multifaceted.

Media portrayals of family members and how those portrayals change or remain stable over time can be read in relationship to shifts in the cultural climate. The real world has experienced a number of changes within the family in terms of composition and the roles undertaken by family members inside the home and out. Some of those transformations are apparent in media depictions of fathers, and others lag behind. Still others appear on the surface to mark progress away from domestic gender stereotypes. Yet, the subtler message of comic failure when husbands and fathers attempt household and parenting tasks may serve to reinforce gender stereotypes by suggesting an innate lack of suitability for these roles.

FEAR REACTIONS

Children and adults often feel fear while being exposed to the media, and that fear can last for varying lengths of time after the exposure. Violence is a typical source of media-induced fears, but other images and themes also provoke fear in viewers, and there are important developmental differences in this regard. A good deal of research evidence has accumulated on the prevalence of media-induced fears, the consequences of exposure to fear-evoking messages, the types of stimuli that evoke fear in different age groups, and the coping strategies that are most effective in reducing the emotional disturbance.

THE PREVALENCE OF FRIGHT REACTIONS TO TELEVISION AND FILMS

Studies of children's nightmares and anxieties produced by media have been reported since the 1930s, starting with movies, then moving to radio crime drama in the 1940s and finally to television in the 1950s. Anecdotes about intense reactions to popular movies such as *Jaws* and *The Exorcist* were prevalent in newspapers in the 1970s, and psychiatric case studies of intense reactions by individuals, sometimes even requiring hospitalization, began appearing at that time. More recent studies confirm that fright responses to movies, television programs, and the news are quite common.

Correlational studies also show that children who watch more television are at higher risk for experiencing anxiety and sleep disturbances.

Two studies of adults' memories of having been frightened by a television show or movie found that many people experience intense fear reactions years after exposure to frightening images in media stories. In both these studies, the presence of vivid memories of enduring fear was nearly universal among college undergraduates. Both studies reported that generalized anxiety, mental preoccupation, fear of specific things or situations, and sleep disturbances are quite common consequences of exposure to the media. Moreover, in a study by Kristen Harrison and Joanne Cantor, one third of the students who reported having been frightened said that the fear effects had lasted more than a year. More than one fourth of the respondents said that the emotional impact of the program or movie (viewed an average of 6 years earlier) was still with them at the time of reporting.

A recent study explored the enduring effects of specific, well-known movies in detail. Joanne Cantor collected more than 500 class papers written by students about their own fright reactions to television programs or movies. She analyzed the content of papers written about the movies cited most frequently

(*Poltergeist, Jaws, The Blair Witch Project,* and *Scream*) and noted how often the anxiety provoked by these movies had changed people's subsequent behavior in real life. Overall, 46% of these students said that the movie had caused nightmares or other sleep disturbances, and 75% reported that it had influenced some area of their waking life. Among the prominent effects on waking life were difficulty swimming after *Jaws;* uneasiness around clowns, televisions, and trees after *Poltergeist;* avoidance of camping and the woods following *The Blair Witch Project;* and anxiety when home alone after *Scream.* More than a third of the students reported effects continuing to the present. What is striking about these responses is that they often continued even after the individuals realized that their responses were irrational. For example, almost as many people who said they were afraid to swim in the ocean after seeing *Jaws* also said they were uncomfortable in lakes and pools, even though they fully understood that these venues pose no danger from sharks. These types of responses attest to the enduring power of emotional memory to reinstate the physiological symptoms of fear even when the person knows at a rational level that he or she is not in danger. Recent research on the neurophysiology of fear demonstrates how indelibly traumatic memories are stored in the brain.

AGE DIFFERENCES IN MEDIA STIMULI THAT FRIGHTEN

Researchers have found that different elements in media messages frighten children of different ages. Using experiments based on principles of cognitive development, these researchers have tested controlled variations in program content and viewing conditions. For ethical reasons, only short excerpts from relatively mild stimuli are used in experiments to observe changes in children's behavior, facial expressions of emotion, physiological responses, and self-reported feelings. To complement these studies, surveys have explored children's responses to more intensely frightening fare to which they were exposed in their natural environments.

The Diminishing Effect of Appearance

As children mature cognitively, their fear reactions are triggered by different types of things in media portrayals. For example, preschool children (approximately 3 to 5 years old) are more likely to be frightened by something that looks scary but is actually harmless than by something that looks attractive but is actually harmful. In contrast, older elementary school children (approximately 9 to 11 years) are not as affected by something that looks scary but are much more influenced by the behavior or destructive potential of a character, animal, or object.

In a survey that asked parents to name the programs and films that had frightened their children the most, parents of preschool children most often mentioned shows with grotesque-looking, unreal characters, such as the television series *The Incredible Hulk* and the feature film *The Wizard of Oz*; parents of older elementary school children more often mentioned programs or movies that involved threats without a strong visual component and that required a good deal of imagination to comprehend. A laboratory study then explored responses to *The Incredible Hulk* in more depth and found that preschool children's unexpectedly intense reactions to this program were partially due to their over-response to the visual image of the Hulk character. When children were shown a shortened episode of the program and were asked how they had felt during different scenes, preschool children reported the most fear after the attractive, mild-mannered hero was transformed into the monstrous-looking Hulk. Older elementary school children, in contrast, reported the least fear at this time, because they understood that the Hulk was really the benevolent hero in another physical form, and that he was using his superhuman powers to rescue a character in danger.

Another study tested the effect of appearance more directly, by creating a story in four versions, so that a major character was either attractive and grandmotherly/motherly-looking or ugly and grotesque. The character's appearance varied with her behavior—she was depicted as behaving either kindly or cruelly. In judging how nice or mean the character was and in predicting what she would do in the subsequent scene, preschool children were more influenced than older children (6 to 7 years and 9 to 10 years) by the character's looks and less influenced than older children by her kind or cruel behavior. As the age of the child increased, the character's looks became less important, and her behavior increased in importance.

The Emerging Distinction Between Fantasy and Reality

As children mature, they not only avoid being frightened by characters' physical features, they also are less responsive to fantastic dangers depicted in the media. They become more adept at distinguishing reality from fantasy and are more influenced by depictions they regard as real. Surveys of parents' reports of their children's responses are consistent with this developmental trend. In general, the tendency to mention fantasy offerings (depicting events that could *not* possibly occur in the real world) as sources of fear decreases as the child's age increases, and the tendency to mention fictional offerings, depicting events that can *possibly* occur, increases. Further support for this developmental trend comes from studies of elementary school children's fright responses to television news, which show that fear induced by news stories increases with age.

Increasing Susceptibility to Abstract Concepts

As children mature, increasingly abstract concepts have the capacity to frighten them. This conclusion is illustrated by findings from a survey of children's responses to the television movie *The Day After,* which depicted the devastation of a Kansas community by a nuclear attack. In a random telephone survey of parents conducted the night after the broadcast of this movie, the level of fear reportedly produced by the movie increased with age. The findings seem to be due to the fact that the emotional impact of the film comes from the contemplation of the potential annihilation of the Earth as we know it—a concept that is beyond the grasp of the young child.

In summary, research on the relationship between cognitive development and emotional responses to media helps predict the types of television programs and movies that are more or less likely to frighten children of different ages. In addition to providing empirical tests of the relationship between cognitive development and affective responses, these developmental findings can help parents and other caregivers make more sensible viewing choices for children.

AGE DIFFERENCES IN THE EFFECTIVENESS OF COPING STRATEGIES

Developmental differences in children's information processing abilities result in differences in the effectiveness of strategies to prevent or reduce their media-induced fears. In general, preschool children benefit more from *noncognitive* than from *cognitiv*e strategies; both cognitive and noncognitive strategies can be effective with older elementary school children, although older children tend to prefer cognitive strategies.

Noncognitive Strategies

Noncognitive strategies are those that do not involve the processing of verbal information and that appear to be relatively automatic. The process of visual desensitization, or gradual exposure to threatening images in a nonthreatening context, is one such strategy that has been shown to be effective for preschool and older elementary school children. In several experiments, prior exposure to filmed footage of snakes, still photographs of worms, rubber replicas of spiders, and live lizards reduced children's fear responses to movie scenes featuring similar creatures. In addition, fear reactions to the Hulk character in *The Incredible Hulk* were reduced by exposure to footage of the actor who plays the character having his makeup applied so that he gradually took on the menacing appearance of the character. None of these studies reported age developmental differences in the effectiveness of desensitization techniques.

Another noncognitive strategy that has been shown to have more appeal and more effectiveness for younger children than for older ones is covering one's eyes during frightening portions of a presentation. In one experiment, for example, when covering the eyes was suggested as an option, younger children used this strategy more often than older children. Moreover, the suggestion of this option reduced the fear of younger children but actually increased the fear of older children.

Other noncognitive strategies involve physical activities, such as clinging to an attachment object or having something to eat or drink. Adults expect these physical techniques to work better for younger than older children, and younger children report using them more often.

Cognitive Coping Strategies

In contrast to noncognitive strategies, cognitive strategies involve verbal information that casts the threat in a different light. These strategies involve relatively complex cognitive operations, and research consistently finds such strategies to be more effective

for older children than for younger ones. Data also indicate that older children use cognitive coping strategies more frequently than preschool children and expect them to be more effective.

The most typical cognitive strategy for dealing with fantasy depictions seems to be to provide an explanation focusing on the unreality of the situation. This strategy is especially difficult for preschool children, who do not fully grasp the implications of the fantasy–reality distinction. In one experiment, older elementary school children who were told to remember that what they were seeing in *The Wizard of Oz* was not real ended up displaying less fear than their classmates who received no instructions. The same instructions did not help preschoolers, however.

For media depictions involving realistic threats, the most prevalent cognitive strategy seems to be to provide an explanation that minimizes the perceived severity of the depicted danger. This type of strategy is not only more effective with older children than with younger children, in certain situations it has been shown to have a fear-enhancing effect, rather than an anxiety-reducing effect, with younger children. In an experiment involving the snake pit scene from *Raiders of the Lost Ark,* prior reassuring information about snakes (e.g., the statement that most snakes are not poisonous) tended to reduce the fear of older elementary school children. However, kindergarten and first-grade children seem to have only partially understood the information, responding to the word *poisonou*s more intensely than to the word *not.* For them, the supposedly reassuring information increased their fear.

Research has explored some of the specific reasons for the inability of young children to profit from verbal explanations, such as those involving relative quantifiers (e.g., "Some are dangerous, but most are not") and probabilistic terms (e.g., "This probably will not happen to you"). It is clear from these studies that it is an extremely challenging task to explain away threats that have induced fear in a child, particularly when there is a strong perceptual component to the threatening stimulus, and when the reassurance can only be partial or probabilistic rather than absolute.

Because it is so difficult to reassure young children who are scared, Cantor published a children's book to illustrate what research has found to be the most effective techniques in reducing young children's fears. In *Teddy's TV Troubles,* a little bear who is scared by something on TV turns to his mother for reassurance. Acknowledging that *words don't always work,* the mother bear leads Teddy through a series of noncognitive coping strategies that, in the end, successfully reassure him.

SHIELDING CHILDREN FROM HARM

As television and movies have become more intense and more graphic in their depictions, parents have sought ways to take more control over their children's exposure to media. The movie rating system developed in the late 1960s by the Motion Picture Association of America (MPAA) has undergone several modifications in response to parents' wishes. In addition, in the late 1990s Congress mandated the manufacture of V-chips in new televisions to permit parents to block programs on the basis of ratings, and the television industry developed a TV rating system designed to work with this new technology. These innovations are only part of the solution, however. Parental education on the effects of the media and media literacy education for children are also critical for preserving children's mental health in today's media environment.

FEDERAL COMMUNICATIONS COMMISSION (FCC), ADVERTISING AND

The Federal Communications Commission (FCC), an independent administrative agency established by the U.S. Congress in the Communications Act of 1934, has jurisdiction to regulate electronic media in the United States, including television, radio, and cable but not the Internet. The FCC enforces rules that limit advertising and other commercial content in children's television programming. The FCC also enforces rules that ban advertising for tobacco products on regulated electronic media and prohibit some forms of gambling advertising on licensed broadcast radio and television stations.

ADVERTISING IN CHILDREN'S TELEVISION PROGRAMMING

In the Children's Television Act of 1990, Congress limited advertising in children's programming to no more than 10.5 minutes per hour on weekends and 12 minutes per hour on weekdays for television broadcasters and cable operators. In response, the FCC made rules in 1991 enforcing these limits and defined *children's programming* in the rule as "[programming] originally produced and broadcast primarily to an audience of children 12 years old and younger." The rule's limits broadly apply to "commercial matter" including paid advertising for products and services. Long-standing FCC policy recommends adequate separation between program content and commercial messages in children's programming to better enable children to distinguish between content and advertising.

When a children's program is associated with a product that is advertised during that program, the entire program can be deemed a "program-length commercial," which qualifies as "commercial matter" subject to the per-hour limits of the FCC rule. For example, the FCC found that a 30-minute cartoon based on the G.I. Joe character became a program-length commercial when a television station aired two advertisements for G.I. Joe toys during the program. The station was fined for exceeding the per-hour limits for advertising during children's programming. The FCC also prohibits *host selling*, which occurs, for instance, when characters in a children's program endorse products or services during the program. The FCC revised its rules in 2005 and restricted the use of commercial websites during children's television programming, but the effective date of these provisions was stayed and remained pending in June 2006.

TOBACCO, ALCOHOLIC BEVERAGE, AND GAMBLING ADVERTISING

Advertising legal but harmful products on television is an issue of concern from the perspective of protecting children and adolescents. The FCC currently enforces federal statutory bans on advertising for cigarettes, small cigars, and smokeless tobacco on all regulated electronic media. However, there is no ban on advertising alcoholic beverages on regulated electronic media.

The FCC also enforces a federal statutory ban on advertising for lotteries and games of chance on broadcast radio and television stations. Exemptions allow advertising for state-operated lotteries and legalized gambling operated by Native American Indian tribes, among other exemptions. However, in response to a 1999 ruling by the U.S. Supreme Court, the FCC quit enforcing the ban on broadcast television and radio advertising of legalized gambling in private casinos.

FEDERAL COMMUNICATIONS COMMISSION, DEREGULATION OF CHILDREN'S PROGRAMMING AND

The Federal Communications Commission (FCC), an independent agency established by the U.S. Congress in the Communications Act of 1934, has jurisdiction to regulate electronic media in the United States, including broadcast television. In 1974, on petition filed by an advocacy group, the FCC declined to adopt rules for children's television programming. In 1984, the FCC reaffirmed nonregulation of children's programming amidst the deregulatory atmosphere of the Reagan administration. Ultimately, Congress passed the Children's Television Act (CTA) of 1990 and required the FCC to limit advertising in children's television programming and to consider whether broadcasters were adequately serving the educational and informational needs of children in their markets before the FCC renewed broadcasters' licenses.

NONREGULATION IN THE 1970s

In 1971, the FCC initiated an inquiry and rule-making proceeding in response to a petition by the advocacy group Action for Children's Television (ACT). ACT petitioned the FCC to ban commercial sponsorship of children's television programs and to require television broadcasters to include a weekly quota of programming for children ages 12 years and younger during specified hours of the day. In a 1974 report and policy statement, the FCC agreed with ACT that broadcast television licensees have a duty to serve the public interest, which includes serving the educational and informational needs of children. However, the FCC declined to adopt children's television rules at that time.

The FCC concluded that banning commercial sponsorship of children's programming would eliminate a primary source of economic support and incentive to broadcast children's programs. Instead of a rule, the FCC chose to rely on continued industry self-regulation of children's television advertising but cautioned broadcasters that the agency would monitor children's programming for excessive commercialization. The FCC also cautioned television broadcasters to maintain adequate separation between content and advertising in children's programming.

The FCC also declined to adopt mandatory quota or scheduling requirements for children's television programming and concluded that the "commercial marketplace" provided adequate incentive to television broadcasters to provide children's programming. The FCC recommended improved efforts by broadcasters in serving the needs of children and indicated that their individual practices in this area were subject to review during license renewal procedures.

NONREGULATION IN THE 1980S AND CONGRESSIONAL RESPONSE

The FCC terminated the proceedings on the ACT petition in a 1984 report and order and again declined to adopt children's television rules for broadcasters. The FCC reminded commercial television broadcasters of their continued public interest obligation to meet the educational and informational needs of children in their markets but concluded that the availability of alternate sources for children's programming, including videocassettes, pay cable services, and public broadcasting, made mandatory national standards unnecessary.

After President Reagan vetoed children's television legislation in 1988, Congress passed the Children's Television Act of 1990, which imposed per-hour limits on advertising in children's television programming and required the FCC to determine whether television broadcasters were serving the educational

and informational needs of children before it renewed broadcasters' licenses. The FCC adopted rules enforcing these provisions in 1991 and 1996, which effectively ended the FCC policy of nonregulation in the realm of children's television programming.

FEDERAL TRADE COMMISSION (FTC)

The Federal Trade Commission (FTC) is an independent administrative agency established by the U.S. Congress in the FTC Act of 1914 to prevent anticompetitive business practices in the marketplace. In 1938, Congress amended the Act to expand the jurisdiction of the FTC to broadly regulate "unfair and deceptive acts and practices." Other provisions in the FTC Act give the FTC jurisdiction over false advertising for foods, drugs, services, devices, and cosmetics. The FTC has six bureaus, including the Bureau of Consumer Protection, which protects consumers against unfairness, deception, and fraud. Within that bureau, the Division of Advertising Practices enforces federal truth-in-advertising laws and includes children's advertising as a focus of enforcement.

DECEPTION

In 1983, the FTC defined *deception* as a "representation, omission, or practice that is likely to mislead the consumer acting reasonably in the circumstances, to the consumer's detriment." The FTC evaluates potential deception in advertising using the perspective of the reasonable consumer. However, advertising that targets children is evaluated for deception using the perspective of the average child in the targeted group.

The FTC has adopted the conclusion that deception in children's advertising "exploit[s] unfairly a consumer group unqualified by age or experience to anticipate the possibility that representations may be exaggerated or untrue." For example, in one case, the FTC brought action against a toy company over children's advertising that depicted a toy doll dancing in an unrealistic manner. The FTC found the advertisement deceptive based on the conclusion that a reasonable child would likely believe, erroneously, that the toy doll actually could dance as depicted in the advertising.

UNFAIRNESS

In 1980, the FTC defined *unfairness* as an act or practice that causes—or is likely to cause—substantial consumer injury that consumers cannot reasonably avoid and that is not outweighed by countervailing benefits to consumers or competition. Subsequently, Congress incorporated this definition by amendment into the FTC Act in 1994. However, FTC jurisdiction to regulate children's advertising with unfairness enforcement—as opposed to charging deception—remains limited. In 1994, Congress also amended the FTC Act to prohibit the agency from enacting any rule that "[children's] advertising constitutes an unfair act or practice affecting commerce."

In the early 1990s, the FTC used unfairness enforcement to obtain agreements from a number of

companies to limit their advertising of pay-per-call services targeted to children. In 1992 legislation, Congress authorized the FTC to make pay-per-call rules, which now restrict pay-per-call advertising targeted to individuals under the age of 18 years and ban targeting such advertising to children under the age of 12 years. In another case, the FTC closed an unfairness investigation of the R. J. Reynolds Tobacco Company in 1994, citing lack of evidence of a sufficient connection between the company's "Joe Camel" advertising campaign and underage smoking.

OTHER AREAS OF CONCERN

In 2000, the FTC began enforcing the Children's Online Privacy Protection Rule, which restricts online collection of personal information from children under the age of 13 years without notice and parental consent. The rule tracks provisions in the Children's Online Privacy Protection Act, passed by Congress in 1998. In addition, the FTC has issued reports to Congress regarding the marketing and advertising of alcohol products and violent entertainment (motion pictures, music, and video games) to children but recommended in those reports continued reliance on industry self-regulation with suggested improvements and continued monitoring.

FIRST AMENDMENT

The First Amendment to the U.S. Constitution states, "Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press. . . ." Courts, legislatures, and legal scholars have written volumes on what this simple phrase means. Generally, adults have full rights to speak and publish what they wish. Children, however, may have somewhat more limited rights. Courts and legislatures have written and interpreted laws to provide additional protection for children, particularly regarding pornographic or indecent material and expressive behavior in schools. Although other areas of concern exist, these two issues are currently the most contentious.

PORNOGRAPHY AND INDECENCY

Indecency on broadcast media has been addressed through legislation and in various judicial rulings. The 1978 Supreme Court case *Federal Communications Commission v. Pacifica Foundation* established that civil punishments were appropriate for broadcasters who broadcast indecent speech during times when children might be in the audience. A radio station in New York played comedian George Carlin's "Filthy Words" monologue, with a warning that it might be offensive to some listeners, at 2 p.m. A father and his son were tuned in, and the father later filed a complaint. The Supreme Court held that this broadcast was indecent.

The Federal Communications Commission (FCC) has established that it is illegal for broadcasters (on over-the-air broadcast stations or on radio) to broadcast indecent content between the hours of 6 a.m. and 10 p.m. *Indecent content* is defined as depictions or descriptions of sexual or excretory functions. Concerned listeners may file complaints with the FCC, and the FCC may fine the offending broadcaster or, in severe or repeated cases, revoke the broadcaster's license.

Protecting children from online pornography is also a legislative and judicial concern. Online pornography is a multibillion-dollar industry, and it is easy for unsuspecting children to stumble upon sexual content. Congress has twice attempted to control the dissemination of online sexual materials to minors. The first attempt was part of the omnibus Telecommunications Act of 1996, the largest overhaul of the Communications Act of 1934. This legislation, named the Communications Decency Act, or CDA, was struck down by the Supreme Court in the 1997 case of *Reno v. American Civil Liberties Union* as unconstitutionally overbroad.

The second act, the Children's Online Privacy Protection Act of 1998, or COPPA, has also been struck down for various reasons at various levels of judicial review. The most recent Supreme Court opinion, *Ashcroft v. American Civil Liberties Union,* decided in 2004, found that there might be less restrictive means than COPPA to achieve the government's goal of protecting children from online pornography. The statute was remanded for further consideration by a lower court in light of new technological developments that might provide sufficient protection for minors while minimizing First Amendment encroachment.

However, a federal statute requiring libraries that receive federal funding for Internet access to install filtering software to block pornographic content was upheld by the Supreme Court in 2003 in *United States v. American Library Association.* The Children's Internet Protection Act, or CIPA, was held as a constitutional way for libraries to limit minors' access to online sexual materials. CIPA does not forbid libraries from offering nonfiltered access; it merely says that the federal government will not subsidize that access. Consenting adults may request that the software be disabled if they wish to access blocked content.

While not expressly intended to control the amount of sexual content consumed by minors, the V-chip, mandated in the Telecommunications Act of 1996 for all televisions 13 inches or larger, can be configured to block sexual themes. The voluntary ratings developed by broadcasters include a rating for sexual activity and themes.

EXPRESSIVE BEHAVIOR IN SCHOOLS AND COLLEGES

There are two opposing legal perspectives on the regulation of student expression in schools, colleges, and universities. The first, more permissive perspective suggests that students have expressive rights similar to those of adults. The lead Supreme Court case in this perspective is *Tinker v. Des Moines Independent Community School District,* decided in 1969. Several students who wore black armbands to school in protest of the Vietnam War were suspended. The Court found that administrative officials could not forbid the expression of opinion within schools without showing that it does something more than elicit mere discomfort or displeasure with the opinion itself. As long as the expression does not interfere with school activities, it is protected.

The second, less permissive perspective provides less protection for students' expression, particularly when published in school newspapers. In *Hazelwood School District v. Kuhlmeier,* decided by the Supreme Court in 1988, administrators removed stories about teen pregnancy and other sensitive issues from a high school newspaper. The Court said that this newspaper was not a public forum for expression and that administrators are entitled to censor nonpublic forums such as school newspapers if the censorship is reasonably related to a legitimate pedagogical concern. Elements to consider in determining whether a student publication is a public forum include how much review is performed by faculty advisors or outside parties.

The standard that has developed from these opposing perspectives is that the greater the extent to which a student publication can be considered to be a public forum, the more protection it has against censorship by administrators. Until 2005, most courts did not consider the *Hazelwood* decision applicable to college or university student media. Two federal circuit courts were on record saying that *Hazelwood* either was not applicable or had little application to college media.

However, in 2005, the Seventh Circuit held that *Hazelwood* might have some application to university student publications. In *Hosty v. Carter,* in finding that a dean did not have liability when she ordered the printer of the Governors State College student newspaper not to print the newspaper until officials had approved it, the court said that the law was not sufficiently established for the dean to have known whether censoring the newspaper was a First Amendment violation. The court did not explicitly apply *Hazelwood*, but it did state that *Hazelwood* might well apply to a nonpublic forum newspaper, even at the college level. The students appealed to the Supreme Court, but in February 2006 the Court declined to hear the case.

The law is unsettled in the areas of protecting children from sexual content and judging the amount of protection available to children's free expression. In coming years, courts and legislatures will continue to struggle with the questions raised by the cases outlined here. It is probably safe to predict that some law restricting minors' access to online sexual content will eventually be passed and found to be constitutional, as the topic remains a hot political issue. However, it is more difficult to predict whether that law will be COPPA or a new, more narrowly written one. It is equally difficult to predict the amount of protection student media will receive, given the intense interest from school administrators, faculty advisors, and student journalists in the outcome of *Hosty* at the Seventh Circuit. *Hosty* reopens for consideration the application of *Hazelwood* to student media at the college level and reaffirms the notion that a publication at any academic level that is considered to be a nonpublic forum is much less likely to be protected against censorship by administrators.

FOOD ADVERTISING, CONTENT IN

The content of food advertising targeting children and adolescents has remained startlingly stable over the past 30 years. Although various modes of advertising to children exist, television has been the predominant mode of persuasive appeals. Since the 1970s, about 50% of ads on television have been devoted to food advertising. Unhealthy foods, such as sugared cereals, candy, and conveniently packaged meals, prevail in advertising, and there are relatively few, if any, advertisements for foods that qualify as "healthy." Food ads typically employ fun and happiness appeals to sell their products rather than describing the nutritional value. Caucasian and minority characters in ads better approximate gender and ethnic groups in contemporary society than in previous years. Rather than providing useful information about the product to audience members, ads targeting children often include unclear disclosures and disclaimers, as in the "part of a complete breakfast" feature of ads targeting children.

PRODUCT TYPES

In the 1970s, Earle Barcus conducted a seminal study on television advertising targeting children, finding that 64% of all ads related to food products. This trend held relatively constant during the late 1980s and 1990s, when two other research teams found similar results, except that ads for toys seemed to have overtaken the candy and snack categories. This slight shift in ad distribution was attributed to marketers' increased use of toy product tie-ins with children's programs following the Federal Communications Commission's deregulation of program-length commercials.

One study estimates that children are exposed annually to as many as 11,000 television advertisements for low-nutrition foods. The overwhelming majority of food products advertised are highly sugared products, such as cereals, candy, snacks, cookies, and drinks.

Some studies have suggested that as few as 31% of food ads directed toward children contain health claims. A study of the actual nutritional content of food depicted in network television ads revealed that 97.5% of foods advertised during Saturday-morning programming and 78.3% of foods advertised on Saturday-evening programming were unhealthy, where *unhealthy* was defined as containing more than 30% fat, more than 360 milligrams sodium, more than 35 milligrams cholesterol, and more than 33% sugar, of the total calories. The sheer number of ads and unhealthy foods represented in ads has been of concern to child advocates and health-care researchers because of young children's inability to discern persuasive intent in ads, and because of the burgeoning issue of child-onset obesity, which leads to numerous health problems in adulthood.

PERSUASIVE APPEALS

Companies use several strategies to attract children's attention to ads. The use of fantasy themes is one such approach. Examples of this type of strategy are an ad for cereal showing children sliding down a mountain of cereal and a depiction of kids being whisked into a tunnel of fruit flavor after they try the product. Such tactics increase the likelihood of attracting children's attention. Whereas many adult advertisements explain the primary benefit or advantage of a product over others, ads targeting children rely heavily on themes of fun and happiness in their attempts to persuade. Children are commonly shown using or consuming the product and having endless amounts of fun, and often the product is shown only momentarily, if at all. The happiness theme, rather than claims about the product itself, is at the forefront of the commercial. For example, one version of an ad for McDonald's shows an animated version of Ronald McDonald walking around the world as a Pied Piper of sorts, with people stopping their activities to join him and have a good time. Another tactic used in ads targeting children is to emphasize the extraordinary taste, flavor, and smell of the product. An example of this strategy is a cereal ad that claims to taste better than real apples because the product tastes "cinnamony sweet."

CHARACTER REPRESENTATIONS

Ethnic representation in ads targeting children has become more equitable in recent years. In the 1970s, Caucasians constituted more than half of all characters, minority representation was only a small percentage—less than 10%—and a combination of ethnicities was used in approximately 30% of total food ads. Minority characters portrayed in ads were often relegated to supporting or stereotypical roles rather than being cast as the main character. More recent studies show that minority characters are more likely to be cast in lead roles than in previous years, and in some cases may be represented in proportions similar to their representation in the general population. During the 1970s, boys typically outnumbered girls three to one in commercials, especially when products were gender specific, such as action figures for boys. More recently, however, there appeared to be equal representation among boys and girls in ads.

DISCLOSURES AND DISCLAIMERS

Disclosures such as "part of a balanced breakfast" are frequently used in children's food ads. Disclosures and disclaimers are used to provide information about the product that would otherwise be unknown to audience members so that they can make informed decisions about the product. Studies show that, despite the recurrent appearance of such disclosures in ads, most children under the age of 8 years are unable to comprehend their meaning as stated. When disclosures are reworded in more child-friendly language, comprehension of the disclosures tends to increase.

FOOD ADVERTISING, EATING DISORDERS AND

Advertising to kids, especially food and beverage marketing, is big business. The media have often been criticized for promoting unhealthy food products and beverages to entice children. The increasing frequency of diagnosed eating disorders among children and youth is a cause of great public concern, and youth obesity has become a major social problem in information societies worldwide. Although research shows that a number of biological, psychological, familial, and sociocultural factors can influence the onset of an eating disorder, in recent years food advertisers and the media have received much of the blame.

FOOD ADVERTISING TO CHILDREN

At the turn of the 21st century, advertisers in the United States spent approximately $12 billion annually targeting the youth market; marketers spent more than $1 billion in measured media alone, with in excess of $4.5 billion spent on promotional efforts that target youth by using sampling, coupons, contests, sweepstakes, and similar techniques. Another $2 billion is devoted to public relations efforts targeting children and adolescents, the building of school relationships, and event marketing.

One of the largest product categories marketed to youth today is food and beverages. Annual advertising expenditures for U.S. food products accounted for $7.3 billion by the year 2000. To place this issue in perspective, the U.S. Department of Agriculture spends approximately $333 billion per year on nutritional education, whereas annual advertising expenditures for confectionary and snack foods alone total at least $1 billion. Food marketers acknowledge the importance of targeting youth and developing positive, long-lasting brand relationships with both children and parents to create brand loyalty in the future. Highlighting this importance, marketers spend just over $3 billion annually to design food product packaging that children will want to purchase.

Critics of advertising junk food to children fault the use of attractive spokescharacters—as well as the use of color, humor, music, and fast-paced presentations—to persuade children to consume. They allege that children often make bad food choices because of the cross-promotional marketing schemes of food and entertainment companies; for example, linking SpongeBob SquarePants with Kraft Macaroni and Cheese or using Nickelodeon characters as toys in and promoters of McDonald's Happy Meals. Critics also cite as problematic the sheer volume of advertisements children view on a daily basis, especially television commercials. Recent estimates are that today's child views between 20,000 and 40,000 television commercials each year. According to Kunkel and Gantz, food products make up roughly half the ads viewed by adolescents. Sugar-laden cereals are the most frequently advertised product on television; other food products often marketed during youth television programming include candy, snacks, cookies, and sodas. In contrast, very few commercials promote healthy food options such as fruits and vegetables. In summary, snack, convenience, and fast foods dominate advertising to children, especially during the television programs children watch the most.

Although television is the medium most heavily consumed by children, other popular media outlets target youth with junk-food ads. Product placements in video games, television shows, and movies are increasingly common, as is the use of global positioning satellites (GPS) capable of reaching children with one-to-one advertising. Moreover, toy manufacturers are collaborating with food companies to provide Jell-O, Barbie, or Easy Bake Oven Little Debbie snack cake kitchens, making food name brands more recognizable to youth. Children now receive promotional offers for junk food through direct mail at home and as spam in their email. School-related food promotions and fund-raisers, as well as vending machines and nationally advertised fast food companies in school cafeterias, complete a food-saturated advertising environment some kids obviously cannot resist.

EATING DISORDERS

The prevalence of eating disorders affecting adolescents and teens is rising at an alarming rate in the United States and other postindustrial countries. According to the National Institute of Mental Health, more than 5 million Americans suffer from eating disorders each year; the National Association of Anorexia Nervosa and Associated Disorders suggests that this number is closer to 8 million. Females account for 9 out of 10 people with eating disorders. The Center for Mental Health Services estimates that

95% of those who have eating disorders are women between the ages of 12 and 25. Although eating disorders typically begin in the teen years, studies now show that eating disorders have been documented in children as young as 8 years old.

The two most commonly diagnosed eating disorders are anorexia nervosa and bulimia. Both eating disorders can cause bodily harm and mental despair—and in severe cases, even death. Anorexia nervosa is characterized by the refusal to eat enough food to maintain body weight at the minimum for age and height. Sufferers experience an intense fear of gaining weight. Bulimia often entails a pattern of bingeing (eating large quantities of food in small time intervals) followed by vomiting behavior or purging, the use of laxatives, fasting, or overexercising.

THE INFLUENCE OF FOOD ADVERTISING AND MEDIA

The relationship between mass media and eating disorders has been frequently studied in communication and health. Many researchers have attempted to establish a link between the frequency of viewing unrealistic, hyper-thin models and characters and feelings of dissatisfaction with personal weight and body image or have examined media exposure with respect to perceptions of the relationship between thinness and success or success and beauty. Studies show that media do not adequately represent average body frames. Media often portray unrealistically thin media characters that young girls, in particular, desire to emulate. Harrison and Cantor (1997) found that adolescent females who watch more television are more dissatisfied with their bodies. Adolescent females who watch a lot of television are also more likely to show symptoms of eating disorders than are females who view less television. According to officials in Fiji, a sudden increase in anorexia and bulimia coincided with the arrival of television in their country.

Reading women's magazines is also a strong predictor of body image problems. A study by the National Institute on Media and the Family found that women's magazines showcase 10 and 12 times as many advertisements and articles on weight loss as men's magazines do. Levine (1998) reported that 46% of girls in the 5th through 12th grades reported wanting to lose weight because of magazine images; 69% of girls in the same sample reported that magazine pictures influenced their impression of the ideal body shape.

To counteract the rising number of eating disorders, the U.S. government is now recommending cuts in food advertising to children and emphasizing the benefits of a healthy diet and exercise in maintaining an average body weight. Whether this strategy will be effective in counteracting prevailing trends in advertising and youth obesity has yet to be determined.

FOOD ADVERTISING, GENDER, ETHNICITY, AND AGE

According to *Advertising Age*, U.S. advertising spending for food, beverages, and candy in 2004 was approximately $6.8 billion, placing it sixth highest among all product categories. Some researchers have suggested that advertising for food products accounts for as much 10 to 15 commercials per viewer every hour on TV. Because many food advertisers realize that young people are a very important target audience, programming and media geared toward children and adolescents also tend to contain a high percentage of advertisements for food products. Although much academic and policy research in this area has focused on the nutritional value of the advertised food products in relation to children's health, there have been

some major investigations into the aspects of gender and ethnicity portrayals in TV food advertising targeted toward youth.

In this area, studies involving gender typically have investigated the roles of gender among several dimensions: the main character(s) in the ads, the main product user(s), the announcer, and any stereotypes cast by the products themselves. Most of this research indicates that food advertisements aimed at children tend to skew toward a male-dominated environment. In a study about advertising on children's TV in both the United States and Australia, Beverly A. Browne concluded that gender preferences for males dominated in both countries, although the bias was even greater in the U.S. commercials. The gender preferences displayed in both countries included more male actors, more male product-users, and a greater number of male voice-overs.

A similar study examined advertising on children's TV in both the United States and Great Britain. In keeping with the findings just discussed, Adrian Furnham, Staci Abramsky, and Barrie Gunter discovered that males were more numerous than females in both American and British commercials and that males generally occupied more central or authoritative positions. Although it was a cross-national comparison, the authors found many more similarities than differences between the ads in the two countries. They took this as evidence to suggest that the bias toward male-dominated content actually should be a basic concern the world over, not just in the United States. Furthermore, citing the general concern about children's susceptibility to media messages, the authors contended that the type of gender casting typical in much TV or media is especially important regarding young people because they may be very impressionable as they begin to form their views of the world.

Interestingly, although the advertising content analyzed in these studies did not focus on food advertising per se (but contained many commercials for food by default because the product category is so heavily marketed toward younger populations), one study specifically investigated gender portrayals in food advertising aimed at children. Authors Nancy M. Childs and Jill K. Maher reported that, when compared to nonfood advertising aimed at children, there was greater male domination in the areas of voice-overs (announcers), product users, and main character roles in food advertising on children's TV programming in the United States. The authors suggested that this finding was particularly curious because food is inherently a gender-neutral product. Therefore, they stated, to favor a male perspective in advertising for such a product likely reflects a larger cultural bias on the part of most advertisers rather than conscious decision making specific to the marketing of particular products.

Furnham, Abramsky, and Gunter also investigated ethnic factors in their study of children's TV ads, many of which were related to snack food, fast food, and breakfast cereal. As might be expected, the vast majority of the ads in both the United States and Great Britain featured white actors (both male and female). Black actors appeared in a distant second number of ads, but this number far exceeded the number of ads containing Asians or Hispanics. For all ethnic categories in both countries, more males than females appeared in the ads, except that no ads featured Hispanic males in the Great Britain sample, whereas three featured Hispanic females.

Although most food advertising may contain primarily white actors, food companies—especially those who make packaged food and fast-food items—clearly understand the increasing value of younger, more ethnically diverse audiences and therefore are pursuing heightened marketing efforts to reach them. In the United States, most of these types of campaigns emphasize niche-specific media strategies, such as cable TV advertising, although some companies are hoping that the "newer" programming available on prime-time network TV can reach a wider segment of the young or ethnic markets. Regardless of media strategy, most successful campaigns by food marketers try to tap the younger and ethnic audiences by supporting traditional advertising placements with targeted communication or promotional efforts that effectively appeal to these audiences in nontraditional ways. Common ethnically based strategies currently include incorporating the food companies' brands in various music/CD promotions and concert tours, sports marketing efforts, family entertainment packages, after-school and back-to-school programs, video game promotions, and community-centered campaigns executed in specific ethnic areas.

FOOD ADVERTISING, INFLUENCE OF

The influence of food advertising on children is an immensely complex issue of interest to policymakers, health professionals, and politicians. Given the growing evidence that obesity is a pandemic of growing proportions documented by the World Health Organization, this is not surprising. However, there is often a tendency to simplify, and the rhetoric about negative effects of food advertising to children sometimes goes beyond the facts. Evidence that food advertising to children has an influence on their preferences and choices of different brands is available, but it should be approached with caution given the methodological limitations of the research. Because food preference and choice is but one parameter in the multifactorial problem of obesity in children, there is limited evidence that promotional activity makes a significant contribution to the problem of obesity.

Surveys on the incidence of television food advertising to children have been done regularly since the 1978 analysis by Barcus and McLaughlin. In 1999, Gamble and Cotugna published a review of research over the past quarter-century. The picture that emerges is dominated by foods such as highly sugared breakfast cereals, convenience foods, and food services such as McDonald's and Burger King, with negligible advertising of fresh fruit and vegetables. It is generally agreed that, taken together, these foods would not constitute a healthy diet. However, two issues need to be addressed. Because children are fledgling consumers with allowances that are not spent on supermarket items such as breakfast cereals, children don't directly purchase most of the foods advertised. The market for foods advertised to children is a family market in which children do exert an influence on purchase and consumption patterns. Although household purchase patterns are influenced by children's preferences and their negotiating skills within the family (so-called pester power), this influence is mediated by family styles of communication, negotiation, and socialization. The second issue is that there is no simple mapping between patterns of dietary preference and choice in children and foods advertised in the market for children and young people. Dietary habits are already well established by culture, peers, and family during the period of primary socialization. The range of foods that are advertised is driven largely by the economics of advertising, which is concerned with buying media time for a brand or portfolio of brands. In a lucrative market (such as foods for kids), many brands in, for example, the snacks or sugared drinks sectors are advertised just because there are many companies competing for market share. Ads for fruit and vegetables are few because there is little branding in this sector.

How is the influence of food advertising on children ascertained? Advertising is not limited to broadcast advertising on TV, magazines, or billboards, as there are point-of-sale displays, vending machines in schools, and other techniques to consider. However, most of the research has been done on television advertising to children. In the 1970s and 1980s, the constant barrage of food advertising on Saturday mornings and after school was a great cause for concern—the phrase *kid-vid ghetto* was used to aptly describe the situation at that time. It is extremely difficult, however, to design research that simulates the effect on dietary habits of different levels of cumulative exposure to food advertising, not least because current models of media effects incorporate a child who actively processes information (see Valkenburg, 2004), and it would be difficult to control the various strategies used by different groups of children to view and understand advertising in context.

Researchers have looked at food choice as a function of exposure to advertising in an experimental setting. Typically, these experiments involved children who watched TV ads and then were asked what they would like to choose from a range of alternative brands or products, including the one previously advertised. Research by Goldberg, Gorn, and Gibson (1978) showed that children are more likely to select highly sugared foods if they have previously viewed TV commercials for them, and they are more likely to choose nutritious snack and breakfast foods if they

have just seen pronutrition public service announcements. A subsequent study by Gorn and Goldberg (1980) showed that exposure to more than one commercial for that brand increased the probability that the brand would be chosen, although there was no effect on actual consumption behavior. However, the studies by Goldberg and others, although well designed and ingenious, do not really simulate the realities of consumer behavior within the family for different foods, although they do confirm that advertising influences children's preferences and choices at the level of the brand in the short term.

The evidence that advertising is effective in increasing consumption of whole categories of foods (a generic effect) is more limited. For example, Bolton (1983) used self-report measures on a large sample of children and found that children's exposure to television food advertising significantly increased the number of their snacks and that such viewing had a subsequent and independent effect on the child's dietary efficiency and caloric intake. The effect was small, however, and Bolton concludes that effects of this small size were unlikely to have a serious effect on children's health and nutrition. A 2003 comprehensive review by Hastings and colleagues found modest support for the view that food advertising affects children's consumption behavior.

FOOD ADVERTISING, INTERNATIONAL

Obesity is now considered one of the primary health problems facing children in industrialized countries, and cross-cultural studies have demonstrated that food advertisements are associated with changing eating habits around the globe. A significant amount of research in varying countries has been collected within the past decade that begins to demonstrate the worldwide impact of food advertising. The prevalence of food advertisements is not without consequences. Over the past few decades, obesity rates have increased two- to threefold in most developed countries. It is widely agreed that increases in the prevalence of obesity are related in part to the media environment, although some researchers still believe that a causal link has not yet been demonstrated.

Medical research does demonstrate that 60% of overweight children have at least one risk factor for cardiovascular disease and diabetes; unhealthy eating habits and lack of physical activity are risk factors to which television viewing may contribute. According to the most recent estimates from the American Academy of Pediatrics, children view an average of almost 3 hours of television each day in industrialized countries around the world. As television is the most widely used advertising medium, it is important to examine children's exposure to food messages and the content of these advertisements.

An international study of 9-year-olds in Ireland, Australia, Norway, and the United States showed that TV ads played a significant role in stimulating the interests of children and were successfully able to capture their attention with the techniques used, such as cartoon characters, catchy music, bright colors, and child actors, techniques that are often employed to sell food products.

According to a Japanese study conducted during the 1990s, food preferences and consumption patterns are being influenced in many nations around the world, including the United States, Australia, England, and Japan, partly due to media consumption. This influence correlates with a rise in the intake of unhealthy, processed food products that are frequently advertised on TV. For example, an Australian Food Commission study (1997) reported that 9- and 10-year-old Australian children believed that Ronald McDonald knew what was best for children to eat. Moreover, a recent British study (1999) found that more half of the 828 ads analyzed in the research were for food products, 60% of which were for breakfast foods and other sugary snacks with little nutritional value.

Other developed countries around the world have actively responded to this growing concern. The European Union has recently called obesity a "European-wide problem of epidemic proportions," and the European Commission has committed to making obesity a high priority over the next 5 years, specifically targeting junk food ads with increased regulations and potential bans. In fact, Sweden has already placed a ban on any advertising targeted to children younger than 12 years of age. This is an area in which the United States lags behind, as food advertising to children is a highly profitable segment of the marketing world. Such ads are unlikely to disappear from American television without a significant fight from those companies that benefit from it.

Food advertising has clearly penetrated television programming worldwide. To amend the crisis of child obesity worldwide, improvements are needed in the areas of exercise and eating behaviors. Research evidence demonstrates that media affect eating behaviors and preferences as well as level of physical activity. According to numerous scholars, television has been cited as a factor contributing to higher caloric intake among children. Two possible factors have been proposed that link television viewing to increased obesity rates in this body of research. The first factor is the reduced calorie expenditure from excessive television viewing in place of exercising and engaging in physical activities. The second factor is the increased calorie consumption resulting from the increased desire and requests for food products that are advertised to children on television.

Increases in the amount of time watching television and advertisements have been associated with the higher intake of fattening, sweet, and salty snacks and carbonated beverages, as well as the lower intake of fruit and healthy beverages. The majority of studies in this area show that television food advertisements on children's programming are for highly sweetened products, and the proportion of advertisements from fast-food restaurants is increasing. The bulk of correlational and experimental studies demonstrate relationships among the amount of time spent viewing television, food requests by children directed at parents, food preferences, and the purchase and consumption of foods advertised on television. In addition, several large studies have demonstrated associations between the number of hours of television watched and the prevalence of obesity in children from various countries. With the increasing rates of obesity associated with television advertising, action is critical, and changes in the media environment are needed. The existing body of research in this area clearly shows that this is an international issue.

FOOD ADVERTISING, OBESITY AND

The growing rates of obesity among American children and adolescents have reached epidemic proportions; over the past 40 years, the percentage of children and adolescents who are overweight or obese has nearly tripled. The rates are even higher for children and teens of color, especially among African American and Latina/o youth. These alarming statistics have been met with grave concern by the medical and public health communities, and although the causes are complex and involve both biological and environmental factors, a number of key cultural factors have been identified as potential contributors. These factors include the growth of fast-food restaurants and "super-sized" portions; the increasing variety of foods available that are heavily processed and of low nutritional value; the increasing reliance on automobile travel and corresponding decrease in walking and bicycle riding for transportation; the decrease in school time devoted to recess, sports, and physical education; increased marketing of highly sugared and high fat food products directly to children and youth in venues such as school; and increased time spent using commercial media.

Concerns about the effects of media have largely focused on screen time, including television, videos and DVDs, computers, video games, and movies in the theater. These outcomes can be generally classified as resulting from either *direct effects* (due to the content being viewed) or *indirect effects* (due to the act of watching, regardless of the content). The latter category is primarily the result of displacement effects (i.e., effects of not participating in other activities the children could or would have been doing if they were not watching television), but indirect effects could also be due to other behaviors that typically accompany this type of media use (such as eating junk food).

SCREEN TIME

The most recent studies of media use by children and adolescents conclude that the average 8-to-18-year-old spends 6½ hours a day with media, and that about a third of that time is spent "media multitasking" (e.g., reading and listening to music at the same time). Most of that time involves screen media; listening to recorded music accounts for only about 1¾ hours a day, with less than 45 minutes spent, on average, reading books, magazines, or newspapers. Television remains the dominant medium for children and youth, accounting for an average of almost 4 hours a day (including time spent watching videos and DVDs), with steady TV viewing habits developed by age 2 or 3. Although there has been a slight decrease in children's TV viewing over the past several years, their overall screen time has gone up slightly due to increases in time spent on computers and playing video games. In comparison to screen time, the average 8-to-18-year-old spends less than 1½ hours a day involved in physical activity (including sports or exercise).

FOOD ADVERTISING AND SCREEN TIME

Recent studies have shown a huge increase in the marketing of new food products targeted directly to children and youth, with nearly 10 times more new products introduced in 2004 than only 10 years earlier. The average child sees roughly 40,000 TV commercials a year, and about two thirds of those commercials are for foods, beverages, or restaurants. Numerous studies have shown that the vast majority of the foods advertised to children on television are high in sugar, fat, or sodium. Cereal commercials make up about 30% of all TV commercials shown during children's programs and frequently contain ingredients such as marshmallows, frosting or honey coating, chocolate flavoring, or other forms of added sugar. Candy, ice cream treats, and highly sugared beverages (such as Kool-Aid, soda pop, and "fruit" drinks) make up 15% to 20% of the commercials, and fast-food restaurants that tout kids' meals high in fat and sodium account for another 10% to 15%.

Far fewer studies have been done of food advertising messages on other types of screen media (e.g., video games, movies, and Internet sites) or food product placements in TV programs or movies aimed at children, but those messages are likely to increase in the future. A growing number of food advertisers have also developed websites for children that feature games based on their food products and their associated characters (such as Frosted Flakes' Tony the Tiger); and websites such as neopets.com and candystore.com that are extremely popular with children prominently feature snack foods and highly sugared beverages as part of the scenery or elements of games.

INDIRECT EFFECTS OF SCREEN TIME

Most studies have shown a positive correlation between screen time (especially TV viewing) and obesity among children and adolescents, although

some studies have found only a weak relationship or no relationship at all. The methodologies used in these studies have varied; most longitudinal studies (following children over time, documenting both hours spent using media and measures of weight and physical health) have found a relationship between media use and obesity that increases with age, and some have concluded that screen time was a significant predictor of overweight even when controlled for other factors like social class.

A common assumption about the causal mechanism involved in this relationship relates to the displacement effect: Spending time with screen media displaces physical activity. However, there is a surprisingly weak negative correlation between screen time and time spent on physical exercise; children and adolescents who spend less time with screen media may instead be engaged in other physically passive activities, such as reading, doing arts and crafts, playing board games, or talking with friends.

The indirect effects of screen time, however, also include eating foods that are poor in nutritional quality (especially snack foods and soda pop) while watching screen media. Several studies have shown this to be the case, primarily for television and movies in theaters; concurrent snacking is less likely to occur when children or youth are playing video games or using computers (in large part because their hands are busy).

DIRECT EFFECTS OF FOOD ADVERTISING

Nearly all the research on the effects of food advertising on children and adolescents has focused on television. Numerous studies have shown that TV commercials for foods, beverages, and restaurants do influence children (ages 2 to 12) to prefer high-calorie and low-nutrient foods and drinks (especially those that are high in sugar and fat). They also influence children's requests for and actual purchases of those products, an effect that increases with the age of the child. A growing body of research also shows that these commercials influence children's beliefs about foods and beverages, including beliefs about nutritional claims and healthy diets. Evidence regarding the influence of TV marketing on food and beverage preferences, purchase requests, and beliefs of teens (ages 12 to 18) is less clear and may reflect the broader exposure of teens to different forms of media besides television, although little research has been done on the influence of nutritional messages from other media sources.

Studies have also shown that marketing techniques such as cross-promotion (e.g., using popular TV and movie characters to promote foods and beverages) increase the influence of advertisements on children. These types of celebrity endorsements have great emotional appeal, which transfers to the food or beverage products being advertised, and they also increase children's memory for the advertisement and the product.

A recent summary of peer-reviewed research studies concluded that there is strong evidence that TV advertising negatively influences short-term eating habits of children ages 2 to 11, increasing the likelihood that they will select and eat foods and beverages that are high in sugar and fat or are otherwise of poor nutritional quality. The same report concluded that there is strong evidence that exposure to TV advertising is positively correlated with adiposity (fatness) for both children and teens.

INTERVENTIONS AND RECOMMENDATIONS FOR CHANGE

If screen time causes increased obesity, then it would make sense that interventions designed to decrease children's media time would lead to decreases in weight (or at least slow the rate of weight gain). Several experimental interventions have shown that to be the case, but intervention has been most effective when coupled with an emphasis on increased exercise and improved eating habits. Other recent interventions have incorporated media literacy education to build children's critical thinking skills about the nutritional messages conveyed in food advertising aimed directly at them.

The American Academy of Pediatrics (AAP) recommends no television viewing at all for children under the age of 2 years and limited television viewing for children between the ages of 2 and 10. Other recommendations for parents related to screen time and obesity include not allowing children to eat while watching television and encouraging physical activity during screen time or as an alternative to it.

A number of organizations have recently called for changes in food advertising aimed at children, including the Children's Advertising Review Unit (CARU) and the Institute of Medicine (IOM) of the National Academy of Science. Some of the recommendations involve expanding the industry

self-regulatory guidelines beyond TV advertising to include food advertisements on the Internet and other new media forms, and to eliminate the use of celebrity endorsements and licensed characters to promote foods and beverages that are healthy for children and youth. Other recommendations include integrating healthy food and beverage choices into the storylines of popular TV shows and movies aimed at children and teens, as Sesame Workshop recently began to do with Cookie Monster talking about cookies as "a sometimes food." A recent IOM report also called upon the food, beverage, and restaurant industries to use their effective marketing techniques to promote and support more healthy diet choices for children and teens.

FOOD ADVERTISING, REGULATION OF

Much controversy has surrounded the idea of limiting or restricting advertisers' power to advertise food products to children in recent decades, beginning with advocacy groups such as Action for Children's Television (ACT) petitioning the Federal Trade Commission (FTC) during the 1970s to eliminate ads for sugared food products during children's programming. Although the Children's Television Act of 1990 placed limitations on the amount of time for which advertisements can be aired during children's programming, reducing ad time to 10.5 minutes per hour on weekends and 12 minutes per hour on weekdays, there are no regulations in place restricting the content of advertisements for food or any other products directed at children. The task of monitoring the advertising content directed at children has fallen to a variety of advocacy groups, including the Children's Advertising Review Unit (CARU) as well as the Center for Science in the Public Interest (CSPI).

CONTENT AND EFFECTS OF FOOD ADVERTISING

Although federal restrictions are not currently in place in regard to the content of food advertisements, research evidence indicates that the content of advertisements may in fact influence children and adolescents in a negative manner. According to recent research, more than 60% of the adult population in the United States is overweight, with nearly 30% classified as obese (having a body mass index of 30 or more), and one in three American children is obese. Food advertising is likely to be one of the culprits, as studies show that children desire the food products they see on television, and the large majority of food advertisements are for sugary or salty snacks, candy, and breakfast cereals. The heavy marketing of high-fat foods and foods with low nutritional value to children is often viewed by scholars and researchers as exploitation, as evidence demonstrates that young children do not understand that commercials are designed to sell products and do not yet have the cognitive abilities necessary to comprehend or evaluate advertising messages.

For instance, an analysis conducted by Kotz and Story of 52 hours of advertising aired during Saturday-morning cartoons revealed that two thirds of the advertisements were for fats, oils, sweets, and

high-sugar cereal. None of the ads within the programming were for fruits or vegetables. The majority of the remaining advertisements were for toys. This high level of exposure to unhealthy food ads, combined with children's inability to comprehend the critical differences between advertising and programming content, has created a very desirable target population for advertisers and marketers in recent years.

THE CHILDREN'S ADVERTISING REVIEW UNIT (CARU)

CARU, established in 1974, is responsible for reviewing advertisements appearing in all media outlets directed at children younger than 12 years of age. CARU seeks voluntary cooperation from all corporations and groups advertising to children to avoid advertising that could be interpreted as misleading, inaccurate, or inconsistent with CARU's guidelines. These guidelines are of particular importance for companies that target food advertisements to children, as research has shown that children are likely to trust the information provided by the advertisements, and children will also be more likely to desire food products seen in advertisements. CARU has received criticism for not enforcing strict enough restrictions for the industry and for not trying to impose regulations on advertising by the food industry. CARU supporters pay a fee to belong to the organization, and some of its members include companies that advertise food products to children, such as General Mills, the Kellogg Company, Frito-Lay, Inc., Kraft Foods, and Nabisco.

THE CENTER FOR SCIENCE IN THE PUBLIC INTEREST (CSPI)

The Center for Science in the Public Interest is a grassroots organization concerned with health issues such as food nutrition and safety standards; it is also concerned with the advertisement of food products. It has gained public attention through promoting awareness of the nutritional value of popular food items, such as movie popcorn and items at family restaurants. The CSPI is in favor of policy changes and has been able to successfully effect changes in the laws pertaining to the labeling of food products.

FEDERAL REGULATION

Aside from the self-regulation of child-directed advertising imposed by CARU and the actions of other advocacy groups, the Federal Trade Commission (FTC), the Food and Drug Administration (FDA), and the United States Department of Agriculture (USDA) share authority over the regulation of food products in the United States. Specifically, Section 5 of the 1994 FTC Act clearly prohibits false advertising that could be seen as misleading about content in regard to food products. Additionally, the Federal Food, Drug, and Cosmetics Act forbids the use of any product labeling that is false or misleading. The FTC has official procedures for investigating improper actions, beginning with identifying the misrepresentation occurring within an advertisement, identifying the omission of information for deceptive purposes, considering the advertisement from the point of view of the consumer, and—depending on the observations—in some cases requiring the offender whose advertisement is under investigation to provide additional nutrient information or health claims about the product. If the FTC is convinced that violation of the regulations has in fact occurred, the commission can bring charges against the violator. If convicted, punishment can be a fine of up to $5,000 or up to 6 months imprisonment; harsher penalties can be applied to repeat offenders, with fines up to $10,000 and up to a year of incarceration.

THE FUTURE OF FOOD ADVERTISING TO CHILDREN

With much recent attention in the news media to America's rising childhood obesity rates, and research evidence supporting child-directed food advertising as an evident contributor to what has been referred to an epidemic, it is likely that the possibility of food advertising regulations and restrictions will be revisited in the near future, as the FTC is again holding hearings on this issue. As food advertising to children is a highly profitable segment of the marketing world, it is unlikely to disappear from television without a fight from those who benefit from it. Although CARU and other organizations exist to monitor child-directed advertising, political interests make legislation and enforcement difficult and complicated. But, with the increasing rates of obesity undoubtedly linked to television advertising, action is critical, and changes in the media environment are needed.

FOOD ADVERTISING TO CHILDREN

Food advertisements aimed specifically at children have been of concern to parents and educators since the early years of television. Food advertising comes to children through a wide range of media sources, including TV commercials, food packaging, billboards and point-of-purchase advertising, magazine advertisements, and product placements in TV programs, movies, and video games. Most recently, there has been an explosion of product tie-ins, cross-marketing approaches, and Internet websites designed for children and teens and tied to specific food products or companies (such as Kellogg's "Fun-K-Town"), with games and free prizes. Of particular concern are the free "educational" materials (including reading and counting books for young children) that are sent to schools and day-care centers and prominently feature food products that appeal to children.

Despite this wide range of sources for food advertising messages, TV commercials shown during children's shows and other television programs are still the most direct and most frequent source of food advertising to children—and the only source that has been studied to any extent using empirical research methods. Food and restaurant advertising accounts for more than half of all TV commercials shown during children's programs, and food products are among those most frequently advertised during other late-afternoon, prime-time, and weekend programming as well. And although there is some evidence of a slight decline in the average number of food and restaurant commercials seen by children in recent years, even those studies estimate that the average child sees about 5,000 such commercials a year.

Three aspects of food advertising constitute the primary cause of concern: (1) the types of foods that are shown (and not shown) in advertisements aimed at children; (2) misleading nutritional messages in food advertising aimed at children; and (3) deceptive and distracting techniques used in food advertising for children that mask the true purpose of the message (i.e., to get children to like, request, and buy the food being marketed to them). The harmful effects of food advertising on children's beliefs, attitudes, and behaviors, especially related to the growing obesity epidemic among American children, has been traced—at least in part—to the marketing of high-fat and high-sugar products directly to them.

FOODS ADVERTISED TO CHILDREN

Numerous studies have shown that the foods most frequently marketed to children are high in fat and sugar and low in nutrients; this has hardly changed at all since the 1960s. One recent study found that 83% of the foods advertised on the most popular children's TV programs were for convenience foods, fast foods, and sweets, and that snack time was shown more frequently than breakfast, lunch, and dinner combined. Cereals, which make up about 30% of all TV commercials shown during children's programs, are usually high in sugar (18g or more per serving) and often contain ingredients such as marshmallows, frosting or honey coating, chocolate flavoring, or other forms of added sugar. Even added fruits, such as raisins, may be dipped in sugar to make them extra sweet. Candy, ice cream treats, and highly sugared beverages (such as Kool-Aid, soda pop, and "fruit" drinks) make up another 15% to 20% of the commercials on children's television. High-fat foods, including "kids' meals" at fast-food restaurants, account for another 10% to 15% of the commercials; research has shown that a diet based on foods advertised to children would greatly exceed the recommended daily values for both saturated fat and sodium.

Even the products that fall into other food groups, such as fruit, vegetables, protein, and dairy foods, often contain added sugar or fat. Yogurt for children is usually brightly colored, heavily sugared, and may have

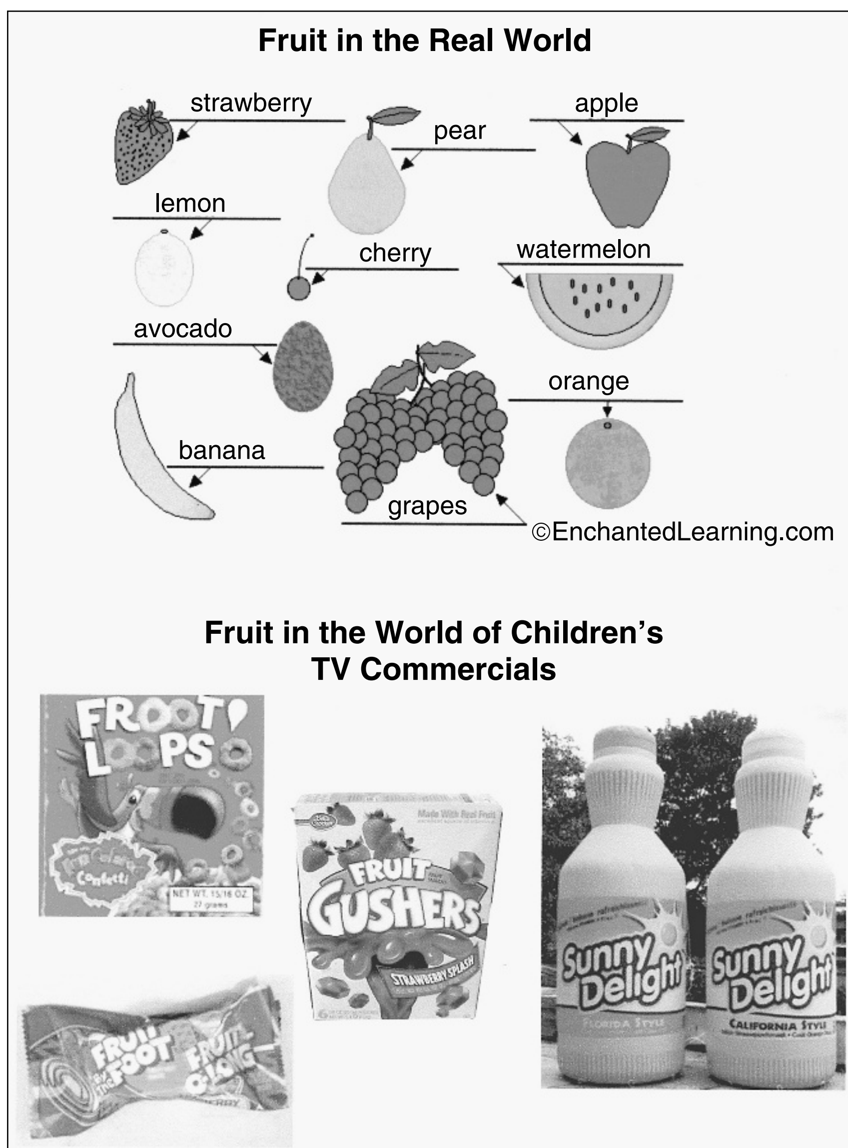

Figure 1 When children are encouraged to eat fruit, adults are thinking of the examples on the top. When children watch television, however, the examples on the bottom are what they are most likely to see; these products contact little or no fruit, despite their names and appearance.

SOURCE: (to come)

added "sprinkles"; "fruit" snacks and drinks are made almost entirely from sugar and water; protein is likely to come in the form of hot dogs or peanut butter with added sugar; and the most common "vegetables" marketed to children are pickles and ketchup. Whole, unprocessed foods (actual fruits, vegetables, or whole grains) are rarely advertised at all and—with the exception of milk—are almost never advertised to children.

MISLEADING NUTRITIONAL INFORMATION

Most food advertising aimed at children contains little or no direct nutritional information about the product. Such advertising often implies, however, that foods are healthier or more nutritious than they actually are. This occurs most frequently with respect to "fruit": commercials that imply, through visual representations, voice-overs, or product names, that the food contains a lot of fruit when it does not (see Fig. 1). Commercials have shown fruit falling out of the sky, fruit bursting out of the food, or the head of a child eating the food turning into a giant piece of fruit—all for products that contain little or no fruit at all. Studies have shown that children do believe that foods such as Froot Loops and Fruit Roll-Ups are fruit. Having been told that they need to eat lots of fruits and vegetables each day, children believe that these products are healthy for them. Most of the "fruit" foods and beverages advertised to children, in fact, contain large amounts of sugar.

Other misleading nutritional messages in children's food commercials include the implication that candy, sugared cereals, and highly sugared beverages are good for you because they give you energy (e.g., sports drinks such as Gatorade). Sometimes, commercials show mothers serving the food or beverage to children with the overt or implied message that the product is "healthy" because mothers feel good that their children are eating or drinking it (e.g., Sunny D, which contains only 5% juice). Food advertisements may also include nutritional statements that are factually true but leave out key information (e.g., referring to candy as a "low-fat food").

Another practice that is misleading involves what is known as the "complete breakfast shot." Current

guidelines issued by the Children's Advertising Review Unit (CARU) concerning advertising to children state:

> Representation of food products should be made so as to encourage sound use of the product with a view toward healthy development of the child and development of good nutritional practices; advertisements representing mealtime should clearly and adequately depict the role of the product within the framework of a balanced diet.

Cereal commercials aimed at children do comply with the latter part of this statement by showing a brief shot of the bowl of cereal, a glass of milk, whole fruit or juice, and some form of grain, along with a verbal statement that the cereal is part of a "complete" or "balanced" or "nutritious" breakfast. However, studies have shown that young children typically interpret this as meaning that the cereal alone is sufficient for a complete breakfast. Furthermore, many commercials incorporate language into the voice-over that is distracting or even contradictory, with a message about nutritious eating (" . . . a marshmallowy sweet part of this good breakfast," "a colorful part of this fun breakfast," or "Pop Tarts, a fun part of this TV breakfast").

DISTRACTING AND DECEPTIVE PRACTICES

Like most television food advertising, food commercials shown during children's programs contain many elements that distract children from attending to the selling intent of the message, including cartoon or humorous spokescharacters (such as Tony the Tiger and Ronald McDonald), story lines emphasizing happiness and fun, super-saturated colors, and special visual or auditory effects. Child-oriented websites tied to food products take this a step further, basing interactive games, puzzles, and sweepstakes around the foods in such a way that masks the central purpose of the activity (i.e., to increase children's positive attitudes toward the product so they will request or purchase it more often).

Of even greater concern to educators is the marketing of "free" educational materials (including books, educational videos, and ancillary teaching aides) that incorporate images of foods of low nutritional quality that are heavily advertised to children. For example, one set of early counting books for children is based on using M&Ms and similar candies to practice counting. Schools—especially those in poor urban districts—are increasingly willing to post advertising for food products in classrooms, in school buses, and on school computers in exchange for much-needed educational funding from those companies. Although there is as yet no empirical evidence documenting the influence of this type of advertising for children, a recent American Psychological Association task force on advertising and children argued that messages presented in a credible educational context may lead children to see these products as more desirable and less harmful than they would if shown standard advertising presentations.

FOOD AND BEVERAGE ADVERTISING IN SCHOOLS

Food and beverage advertising enters schools by a variety of routes, including product sales, direct advertising, indirect advertising, and market research. Each of these routes has variations, and each category is outlined within this discussion. This vast assortment of school-based technologies and techniques brings food and beverage products to students quite prominently within school settings.

PRODUCT SALES

Exclusionary Contracts

"Cola contracts" with major soft drink corporations (primarily Coke and Pepsi) are major entries in this category. A school district, district consortium, or individual school may sign an exclusionary, multiyear contract with the corporation (generally finalized through one of their major bottlers). An initial payment is received at contract signing, and sales quotas are set for each of the years within the contract. By the terms of the contract, the district, consortium, or individual school is expected to meet these sales quotas to receive further contract revenues.

Contract agreements have now been signed in hundreds of school districts, from Colorado Springs to Madison, Wisconsin, to Edison, New Jersey. The Colorado Springs School District, for example, signed a 10-year, $8-million-to-$11-million contract with Coca-Cola. Although contracts have been signed west of the Mississippi River, the trend is moving eastward, and the pace is quickening as schools look to this avenue to cover severe budget shortfalls. By 2006, 240 school districts in 31 states had entered exclusive "pouring rights" agreements with cola companies. This figure was triple the number of contract agreements in 2005.

Lunchroom Contracts

These contract agreements are made with popular fast-food companies (e.g., McDonald's and Taco Bell). Under these contracts, the company serves in the lunchroom alongside the regular cafeteria fare. The products sold in both cola vending and lunchroom contracts match those one would expect to find in either of these venues in the general public.

Fund-Raising Activities

Fund-raising activities constitute a third product sales avenue within schools. The school or one of its internal entities may contract with a major candy company to sell their product(s) as their fund-raising initiative. The company contractually agrees to donate to the school or entity a relatively modest percentage of the sales revenue. Hundreds—in some instances, thousands—of children then fan out across their communities, selling to residents, parents, relatives, friends, and (undoubtedly) themselves, as they try to meet or exceed goals for the fund-raising campaign effort. Hershey, Nestle, and other major candy companies are the most frequent contract participants in such fund-raising efforts.

DIRECT ADVERTISING

Several direct advertising approaches target and reach children and teens at school. Four of the most prevalent are advertising on school grounds and school equipment, ad space sales in school publications, media-based advertising, and product samples.

School Grounds and School Equipment Advertising

The vast array of grounds and equipment ad venues include billboards, marquees, message boards, posters, assignment books, school buses, school bus kiosks, company-donated book covers, and athletic stadium scoreboards. Some schools even place ads atop their schools or atop their school buses.

School Publications

Sales of advertising space in school newspapers, yearbooks, and sports programs are the most prominent food and beverage ad venues among publications.

Media-Based Advertising

Although each of the preceding categories could be called media in the broadest sense, this category refers to television and radio advertising brought directly into the school or its classrooms. Both major

entries in this category target middle and high school students.

Channel One

Channel One enters individual school or district contractual agreements whereby the school or district agrees to broadcast their 10-minute news program and its 2 minutes of commercials in 80% of the classrooms on 90% of the days. The school receives a Channel One-installed satellite dish, two central VCR/DVRs, internal wiring, and a 19-inch television set for each classroom. Food and beverage ads are quite prominent among those carried on Channel One. Some of the most frequently shown product ads include those for candy, snack foods, gum, chips, sports drinks, and colas.

Currently, Channel One is in 12,000 schools nationwide and reaches 8.1 million students on a daily basis. It is more widely watched than any major network and charges upwards of $800,000 for a single 30-second commercial. Roughly 38% of all middle and high schools in the United States are connected to its system, and another 1,000 schools are expected to be added over the next several years.

Star Broadcasting

Following a contractual pattern similar to Channel One's, Star Broadcasting pipes top 50 "hot rock" or "hot country" into schools' hallways, lobbies, and lunchrooms. Advertising matches the ads one would generally find within any top 50 commercial radio log. Again, candy, snack food, and colas are prominent. Star Broadcasting considers its prevalence data to be proprietary, but it specializes in contracting schools and military installations in the United States as well as military installations around the world.

Mouse Pads and Newspapers

Word of Mouse contracts with school systems to supply all the mouse pads for their computers. The supplied pads carry ads, and Internet marketers purchase semester-long visibility at 20,000 to 400,000 school computer terminals. Newspapers-for-schools programs bring a wide range of food and beverage ads to children and adolescents in the schools. As with television and radio, food and beverage ads are quite prevalent in these media entries.

Corporate Samples

Candy and chips samples are among the most prominent food and beverage products given out to students at school. Again, companies such as Hershey and Nestle are among the most prominent sample providers.

INDIRECT ADVERTISING

Corporate-Sponsored Educational Materials (SEMs)

Several companies provide curriculum units to schools. Food and beverage corporations are prominent among them, and their units generally address either the making of one of their products (e.g., one of Hershey's) or the corporation's good-citizen image (e.g., caring for the environment). The key goal is to create brand awareness and a positive attitude toward the product and the corporation.

Corporate-Sponsored Contests and Incentives

One of the most common and familiar approaches is to sponsor a contest, such as book reading, and to provide free product coupons to those children or teens who attain the established goal. Some of the most prominent food corporations using this technique are national pizza companies.

Textbook Branding

With this approach, references to products are placed in textbook content. For example, a student may have a mathematics textbook that contains problems using food products. Questions such as "How many M&Ms . . . ?" are frequent and familiar.

Market Research

This in-school technique relates to polls and surveys, Internet panels, and Internet tracking.

Polls and Surveys

These may be conducted either in paper-and-pencil format or by computer. The range of usage can be broad, including on-site cola taste tests or food product taste tests. Student preferences and family demographics also are surveyed.

Internet Panels

A currently growing corporate advertising technique is to select an online panel of student leaders—students who are very influential among their peers—and give them incentives to share word of a given product among their peers. This technique is related to what is termed *stealth marketing* or *buzz/viral marketing.* Premised on the *ripple effect* or the *spreading viral effect,* stealth marketing presents a product or service in a clandestine way, "beneath the radar" of the consumer. The consumer is influenced by what appears to be a genuine source of information without strings or influence attached. Trendsetters within the marketed group are targeted. They, in turn, spread the word face to face and through Internet chat rooms, weblogs, and their new cousins, vlogs (video) and moblogs (mobile, cellphone). Other types of stealth marketing include brand pushing (folks planted in a store who "happen" to converse loudly about a given product), celebrity (where the celebrity in a bona fide media interview "happens" to endorse the given product or service), and product placement in video games and pop and rap music marketing (where a product is placed in the video game or named in the lyrics of the music). Each of these techniques involves the stealth principle.

Internet Tracking

This method collects data on student hits on given websites and gathers a wide array of information on the individual student, thereby tailoring a product message to that student that will resonate with what the student has expressed.

FORBIDDEN FRUIT HYPOTHESIS

> Adam was but human—this explains it all. He did not want the apple for the apple's sake, he wanted it only because it was forbidden.
>
> —Mark Twain, *Pudd'nhead Wilson*, Ch. 2

The term *forbidden fruit* comes from the biblical account in which God tells Adam and Eve to help themselves to any fruit in the Garden of Eden except the fruit of the tree of the knowledge of good and evil. Adam and Eve eat the forbidden fruit anyway (or perhaps because God told them not to). If something is forbidden, people may want it even more. For example, they may conclude, "Anything I shouldn't have is probably really fun to have." According to the forbidden fruit hypothesis, forbidding something only makes it more desirable and attractive. As applied to media, the forbidden fruit hypothesis suggests that warning labels and restrictions on media access to materials will make them more attractive.

The forbidden fruit hypothesis has much in common with the folk notion of "reverse psychology." According to reverse psychology, the best way to get someone to do something is to tell them to do exactly the opposite. Many parents can testify that this approach has worked with their children. Social psychologist Jack Brehm proposed a more formal theory based on these ideas, called *reactance theory*. The central point of reactance theory is that people desire to have freedom of choice and therefore have a negative reaction to having some of their choices or options taken away by other people or by external forces. The term *reactance* is specifically used to refer to the negative feelings people have in response to loss of freedom (or threats of loss). When people lose a desired option, they respond by increasing their desire for that option, by trying to do what is now forbidden, or by aggressing against the person who deprived them of the option.

Media containing violence, sex, and profanity often contain warning labels (e.g., "Due to some violent content, parental discretion is advised") and restrictive ratings (e.g., "TV-MA: [Mature Audiences Only]"). According to the forbidden fruit hypothesis, warning labels and restrictive ratings will increase rather than decrease the attractiveness of media containing objectionable content.

Reactance effects tend to be bigger when an authority figure tells us not to do something, perhaps because messages from authoritative sources produce more pressure to comply. Research has shown that warning labels are especially likely to backfire if they are issued by an authoritative source. For example, in a 1996 study by Bushman and Stack, a film warning about violent content from the U.S. surgeon general almost doubled the number of people who chose to watch the film.

A meta-analysis by Bushman and Cantor of research on media ratings in general showed that a variety of types of ratings make programming more attractive rather than turning viewers away. This analysis explored the effects of restrictive ratings and descriptive ratings (those that specify the presence of controversial content, such as violence and sex, without explicitly recommending restricted access). Overall, both types of ratings and advisories increased attraction to programs. In addition, the effects were stronger for male participants than for female ones. There was also a curvilinear relationship between the impact of ratings and the participants' age. Up to the age of 8, media ratings indicating restricted or controversial content reduced children's interest. Between the ages of 9 and 22, these ratings increased interest. In participants over the age of 36, media ratings again functioned as a deterrent to viewer interest. Although considerations of reactance might lead to the expectation that restrictive ratings would have a more enticing effect than descriptive labels, the meta-analysis showed that the two types of ratings did not differ in their impact. One explanation for this lack of difference is that, because violence and sex are generally considered taboo subjects, especially for young people, labels indicating their presence send an implicit message that the content deserves to be restricted.

Forbidden fruit effects have been observed in other areas of media behavior. A variety of studies of parental interventions suggest that parental restrictions on media exposure can backfire. For example, in a 2002 study involving adolescents, Nathanson reported that the more parents restricted televised violence and sex, the more positively their children evaluated these contents, and the more likely they were to view these contents with their friends.

Caregiver criticism of media violence also shows differential effects in younger and older children. Most studies involving younger children show reduced acceptance of violence when adults make negative comments during media exposure. However, a 2003 study by Nathanson and Yang found that negatively evaluative statements about witnessed media violence made 5-to-8-year-olds less positive toward the media violence but actually made 9-to-12-year-olds more positive. This backlash and apparent resentment among the older children did not occur when similar content about violence was presented in question form rather than as authoritative statements.

Warning labels and restrictions often function like magnets for media with questionable content in older children, adolescents, and young adults.

FORMAL FEATURES

Formal features are the attributes of media that result from production and editing techniques. Formal features include auditory features (such as music, vocalizations, and sound effects), visual techniques (such as camera zooms, animation, and visual special

effects), action, and pacing. These features interact with the content of programming to influence children's attention, comprehension, and interpretation.

Studies indicate that formal features play an instrumental role in children's attention to television. Perceptually salient features—those that heighten sensory stimulation—such as loud music, rapid pace, and animation, elicit children's attention. Not surprisingly, these features characterize commercial children's programming and advertising. However, research demonstrates that perceptually salient features alone do not necessarily maintain children's attention. For example, one study found that children lost interest more quickly in programs presented in a faster-paced magazine format than did those with less salient features that were presented with a continuous story line.

Children often attend more to features that provide information about the content of a program. Children actively search for television content that is interesting and understandable, and they use formal features as the basis for their selections. Experienced child viewers scan for features such as animation, laugh tracks, and singing that signal programs intended for children or genres they find entertaining. Similarly, children use formal features to determine whether media content is factual or fictional. Very young children may understand that the presence of animation means that a program is "not real." When determining the factuality of a program, older children learn to look for cues such as lower-quality sound and voice-over narration that mark television content as news or documentary genres. Studies have shown that children's perceptions of whether television content is reality or fiction can be manipulated by the use of formal features.

Formal features also influence children's comprehension of media. These features serve as guides to the structure of media content, marking such key narrative elements as changes in time and place. Children comprehend more information from television when visual and auditory features highlight central messages and illustrate abstract concepts. Research on educational programming demonstrates that techniques such as moderate pacing, singing, and children's dialogue help children elaborate on messages and themes, process messages thoughtfully, and rehearse new skills.

Young children tend to have difficulty deciphering the meaning of some formal features, especially those that defy what is possible in the real world. For example, research has shown that young children often interpret instant replays on television as actual repetitions of events. Young children may also have difficulty understanding the codes that signal the end of programming and the beginning of advertising content. The similarity of features used in advertisements to those used in commercial programming may add to the difficulty of very young children in distinguishing between the two.

G

GENDER, MEDIA USE AND

The gender of a child has been found to have a critical influence on media preferences and uses, in conjunction with age, class, and ethnicity. Some researchers even argue that gender differences in media consumption are so substantial that boys and girls can be said to inhabit different cultural worlds.

The development of gender segregation is evident from as young as 2 to 3 years of age, when boys and girls start to develop distinct interests and preferences, including those related to media. Preschool boys already demonstrate a strong preference for entertainment content in television, movies, books, and computer games of action, adventure, sports, superheroes, law enforcers, soldiers, and the like. They move away from preschool educational television programs that present a calmer, nonviolent environment at a much earlier age than girls do, and throughout the elementary school years they maintain a strong preference for action-oriented cartoons, programs, and movies.

Preschool girls, on the other hand, prefer calmer programs that center around characters and relationships, including fairy-tale princesses, performers (dancers, models, singers), animated animals, and the like, and they enjoy preschool educational programs for a much longer period of time. They tend to continue to shy away from violence, horror, and action-adventure content throughout the elementary school years and to react fearfully to violent content in all media forms. Instead, they prefer realistic genres that dwell more on relationships, family situations, and romance, such as teen dramatic series, soap operas, and emotion-filled movies (known by their nickname, “chick-flicks”).

As they move toward adolescence, boys and girls continue to develop tastes that are strongly reinforced by traditional upbringing practices and the cultures in which they are immersed. Boys are preoccupied with downloading computer games that focus on narratives of competition and achievement, surfing pornography sites on the Web, and listening to music genres such as hard rock, heavy metal, and fringe. Girls, on the other hand, spend more time and energy communicating on the Internet with friends and strangers, searching for information on their favorite celebrities and programs, and listening to pop music.

Both boys and girls seem to be attracted to what is accepted in their culture as gender-appropriate technologies, contents, behaviors, and role models. However, most media offer a much wider diversity and quantity of male characters as role models and cater more to boys’ tastes. Broadcasters and producers of other media texts for children prefer to target boys, rather than girls or mixed audiences, for three reasons: First, they assume that boys control viewing habits in the home, as they are more likely to “control the remote-control” and to assert their tastes. Second, producers generally believe that girls will watch boys’ programs, play boys’ computer games, or go to boys’ movies, but not vice versa, as Western culture is more tolerant of girls who are “tomboys” than of boys who are perceived as feminized. Finally, they argue that boys are more susceptible to persuasive messages of commercials for program-related toys and products and spend more money purchasing

them. The marketing potential of children and youth culture is thus directly tied into children's media uses and preferences.

A study of children and youth conducted in the 1990s in 12 European countries demonstrated, too, that boys continue to be more technologically oriented than girls. On the whole, their bedrooms were more equipped with media (e.g., they had their own television set with cable or satellite connections and VCR, computer with CD-ROM and Internet connection, television-linked games and machines, and such). In terms of actual use, however, television appealed to boys and girls to the same degree, whereas computer and television-related gaming was much more prevalent among boys. Girls, on the other hand, listened more to music and read more than boys. Girls had a preference for books and magazines, whereas the boys who did read preferred comics and newspapers.

These differing patterns of usage tend to become more marked as children grow older and are affected more by the strong socializing forces of parents, peers, schools, and the surrounding culture. The family environment often offers strong reinforcements for such segregation. For example, girls often watch the same programs with their sisters and mothers, while boys watch the same programs with their brothers and fathers, thus guarding their separate, gendered space at home. Similarly, traditional assumptions about boys being more technologically oriented than girls is often reinforced at home, where boys may be given priority in access and use of the computer and consulted more about technical aspects of the machines or problems with programs, and where mothers may serve as negative role models.

The gender differences described above have been found across a wide range of studies. However, it is important not to lose sight of the fact that, as perceptions of gender differences in society change, so does the consumption of media. As a result, an overlap seems to be developing in the preferences and uses of boys and girls. For example, many girls love to watch sports, and many boys enjoy soap operas. Many girls are computer "wizards," and many boys are carried away reading about wizards. Thus, the role of media in the construction of gender differences remains fluid, complicated, and ever changing.

GENDER IDENTITY DEVELOPMENT

From a sociological perspective, *gender identity* is an individual's identification as either male or female, which is affected by societal and personal conceptualizations of what it means to be a boy or a girl. Gender identity development is particularly important during adolescence, as gender role identification and adherence to role standards get stronger as adolescents get older. The majority of theories about social influences on gender identity formation focus on how adolescents learn about masculinity and femininity from their families, peers, and social institutions. These theories of gender socialization have found that the media's dissemination of traditional gender roles reinforces traditionally held beliefs that children and adolescents likely also learn from their parents and real-life peers. It should be noted, however, that some research, drawing on evolutionary psychology, considers gender identity from a biological (and genetic) perspective. These studies posit that sex differences result from biological differences between men and women, instead of cultural or social differences.

In recent years, sociological studies began to show that social factors influence gender role development, and that gender identity, rather than being determined

genetically, is primarily socially constructed. These studies began to consider a continuum of gender identity that include an individual's identification as gay or lesbian. According to gender socialization theories, people also learn about gender identities from messages, texts, and symbols in their daily lives that prescribe what is appropriate masculine and feminine behavior.

Discussions of the mass media's influence on gender identity often consider the commercial aspects of American media. The production of media is directly linked to the capitalist economy, which ensures that the messages produced in the media are tied to garnering better commercial profits. Scholars have found that the very concept of subordinated femininity is tied to the market's need to keep women in an insecure and subservient role so that they will continue to purchase goods and support the capitalist structure. Similarly, recent investigations into media portrayals of masculinity have found that these portrayals encourage men to purchase products to maintain both physical and mental dominance.

Rhonda Gibson's study of the news media's portrayal of gays and lesbians found that newspapers rarely discussed the everyday lives of sexual minorities; instead, their coverage often focused on popular gay characters in entertainment media. Other scholars who have analyzed the portrayal of sexual minorities in entertainment media found that these characters are rarely included in adolescent programming, although they are becoming more prevalent in adult programming (e.g., *Will & Grace* and *Queer as Folk*). In an analysis of the portrayal of a gay teen in *Dawson's Creek,* Michaela D. E. Meyer argued that depictions of sexual minorities in entertainment programming typically are based on their interactions with heterosexual peers. Portrayals of gays and lesbians like that in *Dawson's Creek,* Meyer posited, allow the audience to "safely" see homosexuality outside of a context of sexual desire.

Mass communication scholars who have explored the media's role in gender identity development have found that the limited portrayals of gender roles disseminated by the media and other socializing agents help create gender-role stereotypes. Gender-role stereotypes are exaggerations of gender differences that reinforce a false dichotomy between male and female roles while dictating appropriate masculine and feminine behavior. Content analyses of the mass media have found that these gender role stereotypes put forward appropriate occupations, physical beauty, and relationship interactions for males and females. Very little research has explored the media's portrayal of gays and lesbians. Most of the existing research has identified that these portrayals often show stereotypical, negative, and exaggerated gender roles for gays and lesbians.

Although much research into gender identity and the mass media is based on content analyses of various media texts to catalogue existing gender-role stereotypes, some research has connected media exposure to beliefs about appropriate behavior for males and females. For example, previous research has found that increased television viewing was associated with identifying household chores with traditional gender stereotypes (e.g., men mow the lawn and women wash the dishes). Meenakshi Gigi Durham found that young girls used the media to identify to their peers their appropriation of dominant femininity.

Other external influences may encourage youth to have preconceived expectations that may contribute to their interpretation of the media images to which they attend. Durham found that girls negotiated ideals of femininity, including those in the mass media, in their peer groups, which reinforced traditional aspects of gender identity. Yet some scholars have found a negative correlation or none at all between exposure to television and acceptance of traditional gender roles. Scholars argue that the mixed results in the studies trying to connect media exposure to gender stereotypes result from the difficulty of isolating the effects of television viewing from other mitigating factors, such as parents, peers, and other types of media. In reality, however, since the media likely influence parents and peers' conceptions of gender, the media's role in societal stereotypes about femininity and masculinity has likely been underestimated, according to L. Monique Ward.

GENDER ROLES IN MAGAZINES

Gender-role expectations are the behaviors, attitudes, emotions, and personality traits deemed appropriate for each gender; they depend on a socially constructed reality. That reality is constructed by various forces, including the media. Although television may be the most influential medium, magazines also play a part in suggesting appropriate roles for each gender. More often than not, the roles suggested are traditional or stereotypical. Women are encouraged to take care of the home, whereas men are encouraged to do everything else. Over the years, the messages have changed somewhat. Women are told that appearance is of primary importance and are encouraged, through both editorial and advertising, to believe that how they look is more important than who they are or what they do.

WOMEN'S MAGAZINES

In the late 1800s, women's magazines put women on a pedestal and were quite direct in telling women what their roles were or should be. Edward Bok, editor of *Ladies' Home Journal*, wrote in 1893: "The number of women in business who lose their gentleness and womanliness is far greater than those who retain what, after all, are women's best and chief qualities."

Without being quite so blunt, women's home and service magazines (*Good Housekeeping, Ladies' Home Journal,* and *McCall's,* among others) have always emphasized traditional messages, such as family issues, child care, cooking, and housekeeping. Fashion and beauty magazines (*Cosmopolitan* and *Glamour*, among others) focus not only on fashion and beauty but also on male-female relationships. In the 1970s, a new breed of magazine came along. With titles such as *Working Woman* and *New Woman*, they offered hope for content slightly less traditional than the older magazines. However, a 1995 issue of *New Woman* contained 12 pages of makeup advertisements before the table of contents and regularly run columns on fashion and beauty. The emphasis on fashion and beauty does more than suggest to readers—of any age—that looking good is of utmost importance. Who a woman is matters less than what she looks like.

Magazine research focuses primarily on women in advertisements, articles, and short stories in relation to men and occupations. Butler and Paisley (1980) summarized the research up to 1980. They found that, in articles, working mothers were portrayed unfavorably, traditional marriage was emphasized, and if women worked, they did so in low-status jobs. In short stories, few married women worked, and those who did work were primarily looking for husbands. In advertising, men had more roles, were more often employed, and more often had higher-status positions than did women.

Research after 1980 uncovered some changes, in part because of the birth of such nontraditional magazines such as *Working Woman* and feminist magazines such as *Ms*. The traditional magazines, too, have changed the world of women's magazines, if at a snail's pace. In the 1980s, more women were shown working outside the home and in a more positive light, as Ruggiero and Weston noted in a 1985 article. Analysis by Loughlin in 1983 found that, in fiction, the numbers of women with careers increased, and career women were not unsympathetic characters. On the other hand, the dependent heroine—defined as one who depends on others for identity or survival—has long been a part of women's magazine fiction and was found as late as 1997. In Peirce's study, fewer than half of the main characters solved their own problems and thus were dependent on others to solve problems for them.

MEN'S MAGAZINES

Men's magazines in the past focused on activities such as sports (*Sports Illustrated*) or naked women (*Playboy*), and they did not in the least resemble women's magazines, the sole purpose of which was to create insecure consumers. Now, men's magazines are morphing into women's magazines for men. *Men's Health* devotes much attention to physical self-improvement; magazines that have always had fashion pages, such as *GQ* and *Esquire,* are directing their attention to other matters of men's appearance. All this attention to men's appearance has produced men who, as women have done for years, now worry about appearance issues. Hatoum and Belle (2004) found that reading men's magazines was associated with concerns about muscularity and general fitness, beauty product use and dietary supplement use.

Some researchers, such as Anderson and DiDomenico, argue that the appearance messages are still gendered: Women are bombarded by messages that urge them to lose weight and become reed thin, whereas men are encouraged to bulk up. In 1999, Milkin, Wornian, and Chrisler examined magazine covers for gender differences and found that women's magazines were more likely to contain blurbs about diet, exercise, and cosmetic surgery, whereas men's magazine covers talked more about the outside world and less about changing one's body shape. Articles on weight loss were rare in the men's magazines. Effects of these differences go beyond dissatisfaction with one's body shape. Despite more attention in the media to men's appearance, what men do is still more important than what their muscles look like. Women, particularly young women, are likely to internalize the mediated messages of the thin ideal and attempt to reach it through dangerous dieting methods.

GENDER ROLES IN MUSIC

In contrast to biological differences in reproductive organs between females and males, gender differences and the roles we assign to them are socially constructed and learned sets of behaviors and perceptions. The role of music in such a construction of gender perceptions is particularly important, as it is a dominant aspect of preadolescence and adolescence. Music is heard in all forms of media and is particularly accessible when downloaded from the Internet or through its adaptation to visual forms, such as music video clips broadcast on MTV (the Music Television channel). Music is used by youth for leisure, tension reduction, and mood control. It is a resource in their search for individual as well as group identity and solidarity and aids them in expressions of self, independence, and intimacy by appealing to many of their concerns, rebellious urges, and sexual drive. It provides emotional support and helps young audiences deal with the anxieties of growing up. Female and male celebrity singers alike serve as role models for

identification and imitation and are idolized by children and youth. For example, the way music performers are portrayed defines for the young viewers what is "normal," what is accepted in their society, and therefore what wins positive reinforcement, whereas what is exceptional and deviate is viewed negatively. As a result, such images have significant potential to contribute to young audiences' developing identities as females and males, their expectations from each other and from themselves, and their attitudes toward society's norms.

Many of the studies that have examined the portrayals of women and men in various musical genres have found that video clips of pop and rock music, in particular, as well as most mainstream television genres, portray a social world that systematically differentiates between the genders. On the whole, men are identified with "doing" in the public sphere and are portrayed through characteristics such as activity, rationality, forcefulness, independence, ambitiousness, competitiveness, achievement orientation, and higher social status. Women, on the other hand, are associated with "being" in the private sphere and are characterized as mostly passive, emotional, caregiving, childish, sexy, subordinate to men, and of a lower social status. The occupational roles presented in music videos, too, are often stereotypical: On the one hand, men are presented mostly performing manual labor, involved in law and order, and in high-status roles; women, on the other hand, are assigned traditional service, secretarial, and caregiving roles.

The external appearance of women, more specifically their predominant portrayal as a sex objects, is highlighted in the lyrics of songs, in the performers' provocative appearance and revealing clothing, in the association with sexual objects and settings, in camera angles that present them as objects of the lustful gazes of others (men, in particular). Even when highly visible and successful, female performers most often exhibit their independence, assertiveness, and power through their sexuality. The debate over the provocative video clips of the American super pop star Madonna in the 1980s and 1990s illustrates this theme: On one hand, Madonna's media image was that of an independent woman resisting society's ideological constraints that allocated women either the role of "virgin" (and the associated traits of asexuality, modesty, caring, submissiveness, passivity, delicacy, dependency, and so forth) or that of the "whore" (the independent, assertive, sexual woman who is provocative, active, and powerful). In presenting herself thusly, she consciously portrayed herself in various nontraditional gender roles, refused to be manipulated by men, and transmitted a sense of control over her own image and destiny. On the other hand, it has been argued that her struggle for independence remained constrained within the realm of sexuality and appearance that lies at the heart of the subordination of women.

Similarly, the Spice Girls—a British-manufactured, all-female pop group that had an unprecedented success in the global popular music market of the late 1990s—advanced the concept of "Girl Power" in popular culture (i.e., the celebration of the mental and physical strength of young women). Although portrayed as representing a variety of forms of possible femininity—whorish, childish, sporty, wild, and snobbish—as valid options to which a girl could aspire and imitate, the message of the five Spices was that one could succeed with such aspirations—as long as one adheres, first and foremost, to a particular glamorous, sexy look.

Portrayals of men, too, are often quite restrictive and traditional. They continue to be associated with aggression, adventurousness, and sexual lust, particularly in rock and roll and heavy metal music (often nicknamed "cock-rock" for celebrating traditional stereotypical masculinity and a misogynist worldview). This association is highlighted through the lyrics, the appearance and settings of the performances, a variety of audiovisual techniques, and of course, a behavioral repertoire that includes a disregard of rules, purposefully aggressive and abusive treatment of others, and reduction of women to their sexual potential.

Obviously, many exceptions to the above description can be found. Not all music directed at "teenyboppers" (preadolescent girls for whom consumption of music is mostly associated with practices such as dancing, talking with other girls, dreaming of romance, and consuming related goods) is about romantic heterosexual love, vulnerability, and self-pity. Indeed, many male singers, particularly those who appeal to young girls, manufacture themselves in the spirit of "new man," sensitive, capable of expressing feelings, and not aspiring to dominate women and other beings. Popular music has gradually developed as a site of cultural struggle over multiple gender and sexual identities, including gay, lesbian, and androgynous ones, as well as over ethnic and cultural identities. Yet, the studies that performed content analyses

of the various elements in music videos confirmed that traditional gender roles, although slightly on the decline, have remained dominant over the past 20 years. The influence of such portrayals on gender-related attitudes of children and youth has been documented in a variety of studies examining issues such as attitudes toward sexual relationships, drive for thinness, expressions of aggression, emotional dissatisfaction, and the like.

GENDER ROLES ON TELEVISION

During the past 50 years, there have been significant changes in the roles of men and women in society, as well as in our sources of information and entertainment. Although there have been some changes in the media portrayal of gender roles, television's images of sex roles have not kept pace with the changes in the roles, status, and aspirations of men and women. Gender-role images have remained remarkably stable, particularly in children's cartoons and during prime time, when much of the viewing by young people takes place. Women, children, and adolescents are underrepresented in television media, despite some changes in this area over time. Overall, television is overpopulated by men, with some differences by program genre. Women are least likely to be cast in action programs and most likely to be cast in dramas and situation comedies, and similar stereotypes are common in children's programming as well.

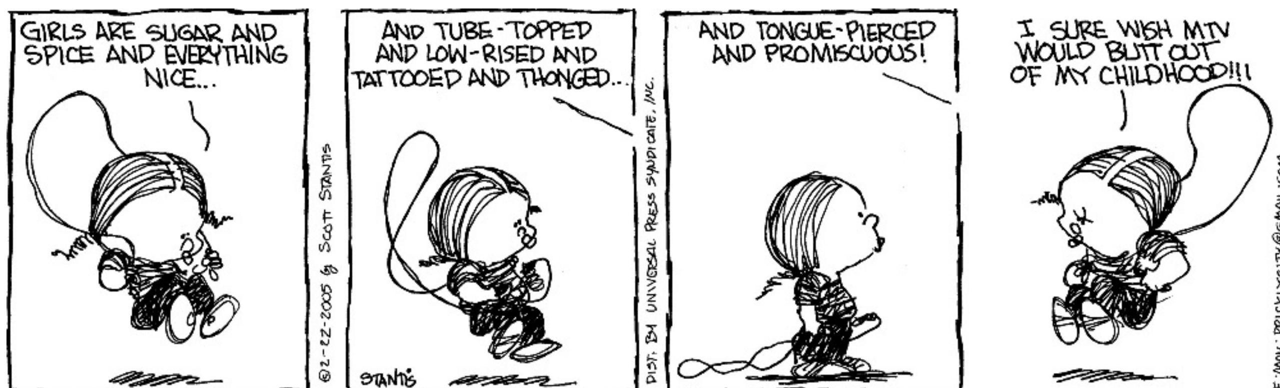
PORTRAYALS OF WOMEN AND MEN

In study after study, men have outnumbered women in prime-time dramatic programming, although the underrepresentation of women on television has decreased to some extent in the past 50 years. The earliest studies of network television broadcast during the early 1950s found three men for every woman. Most of the studies conducted during the 1970s and early 1980s found a high degree of consistency in the television world's demography, with men typically outnumbering women by three to one. More recent studies put the ratio at somewhat less than two to one. There are, however, differences by program genre, with situation comedies having a more equitable male-female mix and action programs having more men than women.

Although television characters have continued to move toward greater representation of women, the numbers still favor men in most program genres. The underrepresentation is found in programs that are new each season as well as those that have been on the air for several years. Moreover, except in situation comedies, women are often cast in minor roles rather than major roles. In 1999, Nancy Signorielli and Aaron Bacue found that the proportion of women in leading and supporting roles increased significantly and steadily between 1967 and 1998, moving from 24% of the characters in 1967 to a high of 43% in 1996 and down to 38% in the spring of 1998. There is also some evidence that some of the programs of the 1990s present more negative than positive characterizations, compared to programs seen in the early years of television.

Similar patterns are found in cable programming, even though cable, because of its numerous channels, has been heralded for its likelihood to provide greater diversity. Nevertheless, the patterns of underrepresentation in broadcast programming are also found in cable programs, with males continuing to outnumber women by two or three to one. The male-female distribution is even more lopsided when programs are examined that air during the prime-time hours on channels that can be received only by cable (i.e., programs not found on the network broadcast channels).

Women in prime time are almost always depicted as younger than their male counterparts who, in turn, are portrayed as older and wiser. Moreover, as female characters age, they become decreasingly significant to the plot, and the few older characters who appear typically lack clearly defined roles. In addition, as



characters age, the life cycle roles of men and women differ: Older men (65 or older) maintain their positions as active, settled, mature adults, yet older women are more likely to be designated as elderly.

The media, particularly television, rarely cast unattractive people in any roles. The images of women's and men's bodies are very stereotyped. The women on television typically have thin, almost perfect bodies. Their weight is judged as average or below average, and very few (fewer than 1 in 10) are even somewhat overweight. Moreover, these characters, particularly those who are quite thin, are often told that they look good, which serves to reinforce the ultra-thin image. On the other hand, the media ideal for men has become more muscular. Last but certainly not least, women on television are more likely to have blond, red, or auburn hair than black or brown hair.

Signorielli (1997) found that the programs favored by adolescent girls present rather mixed messages. Many female characters are positive role models, independent women who can solve problems. Yet, these same programs contain many stereotypical messages about relationships, careers, and appearance, particularly for the young women characters. For example, 4 out of 10 of the men are seen "on the job," compared to only 1 in 4 of the women. Similarly, 4 out of 10 of the women, compared to about 1 in 3 of the men, talk about specific romantic relationships, and 1 in 4 of the women, compared to fewer than 1 in 5 of the men, are seen dating. The women in these programs also are more likely than the men to participate in activities best described as stereotypically female: grooming or preening, doing dishes, cooking, and shopping.

PORTRAYALS OF CHILDREN AND ADOLESCENTS

Children and adolescents have been consistently underrepresented in prime-time programs. Children who are 10 or younger make up about 15% of the U.S. population but only 1% of the characters in prime-time programs, equally divided between boys and girls. Children on television typically play comic roles and are less important than the adult characters. Children, particularly the young boys, are more likely to be victims of violence than older characters. Adolescents make up 14% of the U.S. population, evenly divided between those in the early and later adolescent years. On television, early adolescent boys and girls represent fewer than 3% of the characters, whereas older adolescents (between the ages of 15 and 19) make up 10% of the characters. Interestingly, older adolescent girls appear more frequently than older adolescent boys.

Nancy Signorielli (1987) found that children and adolescents in prime time typically are "good" or "successful" rather than "bad" or "unsuccessful," and younger characters are often in light or comic roles compared to serious ones. They are also found in situation comedies or serious dramas rather than in action-adventure programs. In addition, family life is more important for children and adolescents than for older characters in prime-time programs.

CHILDREN'S PROGRAMMING

Female characters are especially shortchanged and underrepresented on children's programs. Research

has consistently found that men outnumber women by four or five to one in cartoons and that, once again, females are presented in very stereotypical roles. Gender-role portrayals also do not differ in programs based on toys, compared to those that have no relationship to children's toys. Similarly, in children's programs males tend to be aggressive and are often told that their behaviors are not appropriate. Public television programs for children, although better on some dimensions, still fall short in relation to basic demography. Female characters are underrepresented, although their roles are not as stereotyped as those in programs on broadcast television or cable.

Even though female underrepresentation and many stereotypes were present in the cartoons of the 1990s, there have been some changes. Female cartoon characters found in the cartoons of the 1990s are more assertive, intelligent, and independent and are seen in more leadership roles than female characters in the cartoons of the 1970s and 1980s. Nevertheless, female characters are also more likely than male characters to be portrayed in traditionally stereotypic ways; they are more emotional, romantic, affectionate, domestic, supportive, and polite. Male characters also changed during the 1990s; today, male characters are presented as more intelligent, more technical, more aggressive, and as asking and answering more questions but bragging less. Continuing the stereotypes prevalent in cartoons, male characters in traditional action and comic cartoons are more aggressive than the female characters. On the other hand, there are fewer gender-stereotyped behaviors in the educational and nontraditional children's cartoons of the late 1990s.

Although the basic message about gender roles on television relies heavily on stereotypes, it would be incorrect to say that change had not occurred or that nontraditional women do not appear on television; it is just that these images are not found consistently. Most of us can easily cite examples of women who are not stereotyped. Yet, some of the programs of the late 1990s and into the 21st century (e.g., *Ally McBeal, Felicity*) have female characters who break with the stereotypes on one dimension (e.g., occupation), but fall back upon traditional stereotypes when involved in or dealing with romantic relationships. Similarly, some of the recent cartoons geared toward young girls (e.g., *Powerpuff Girls* and *Wings*) that show girls in more aggressive and assertive roles also have the girls look to male characters for help.

The underrepresentation of women and the gender stereotypes in television send a clear message to audiences: Women are not as important as men or are only important when viewed in the narrow confines of situation comedies. It thus seems logical to conclude that, until women are shown frequently and in numerous roles representing the full range of their capabilities and experiences, the effects of television on conceptions of gender roles will remain deleterious to true social equality of men and women.

—Nancy Signorielli

GENDER ROLES IN TELEVISION COMMERCIALS

Although gender stereotyping in television advertising has decreased somewhat since gender roles in television commercials were first studied in the 1970s, such stereotyping remains today, especially in advertising on American television. However, there is some evidence that adolescents are exhibiting critical thinking in viewing such ads.

EARLY STUDIES OF GENDER ROLES IN TV ADVERTISING

In 1941, NBC and CBS were granted commercial licenses for their New York stations, but it was not until after World War II that commercial television began to flourish and expand. In 1951, the entire United States was linked to network television. It was not until the 1970s, however, that concerns about television's effects escalated and researchers began to examine not only television programming but also the commercials that supported television programming. Gender differences in commercials became a popular area of study, with researchers examining numbers of women versus men in advertisements, types of products both genders endorsed, occupations portrayed, voice-overs and ages of characters.

Gender stereotypes were quite prevalent in the 1970s. Men were the spokespeople for all types of merchandise except cosmetics and household products and were the voice-overs at least 90% of the time. Women in commercials typically were housewives, whereas men had a variety of occupations. Courtney and Whipple's 1974 examination of four studies found that women were overrepresented in family and home settings and were most often seen performing domestic tasks. Men usually di dn't demonstrate products—they were often shown benefiting from tasks performed by women—and dominated in entertainment, business, sales, and management occupations.

GENDER ROLES AFTER THE 1970s

More recent studies have found similarities and differences when comparing advertising in other decades with the 1970s. Women were still more likely to be the product representatives for domestic products, and men were more likely to represent no domestic products. Men did 71% of voice-overs, which is lower than the 90% of previous decades. In 1995, Pierracine and Schell also found a decrease in male voice-overs to 70%, as well as more atypical than stereotypical roles for women. Stereotypical roles included homemaker, secretary, and nurse as well as situations in which the woman is viewed as a victim, a nag, or a scatterbrain or in which the woman is not in charge.

In 2003, Rouner, Slater, and Domenech-Rodriguez examined the content of beer commercials and number commercials and found that a majority of the beer commercials portrayed traditional gender roles and sexist content. Number ads were evenly divided between sexist and nonsexist content. The authors wanted to know how adolescents reacted to such ads and found that they were critical of the ads depicting women in stereotypical and sexual roles, with females more critical than males.

GENDER ROLES IN CHILDREN'S TELEVISION ADVERTISING

Much of the research on advertising directed at children has found that the ads are gender stereotypical. Most studies look at gender of the main character in the ad, the gender of the voice-over, the gender of product user, and whether the product itself is gender stereotyped. The product user is more often male, and male voice-overs are much more prevalent than female voice-overs. In cross-cultural studies, it has been found that, although other cultures also stereotype, there are more gender stereotypes in American advertising. Typically, there are more ads directed at boys rather than at girls; girls' ads use more in-home settings, and boys' ads use more out-of-home settings.

In 2003, Maher and Childs undertook a longitudinal analysis of gender roles in children's television advertisements and found that gender stereotyping, although not quite as prevalent as in previous decades, is still present in the 21st century. They determined that there is more gender equality in the number of ads targeting one sex or the other but that males still outnumber females as the dominant product user, voice-over, and main character.

Two studies looked at gender and advertising spokescharacters, the animated characters used as product representatives, such as Tony the Tiger and the Energizer Bunny. Spokescharacters are prevalent in commercials directed toward children. The first study, conducted in 1999 by Peirce and McBride, found that most spokescharacters were male: 30 of 39 were male; 2 were both male and female; 2 were female (Mrs. Butterworth and Aunt Jemima); and 5 were judged neither male nor female. The neutral characters were the Scrubbing Bubbles, Snuggles Bear, Cheerios Bee, the 7-Up Dots, and Toilet Duck. A second study by Peirce, in 2001, found that this does not have to be the case, according to participant ratings in an experimental setting. The spokescharacter was better liked when the gender of the spokescharacter matched the gender of the perceived target audience. A vacuum

cleaner as spokescharacter was cuter and more likable as a female than as a male, and a male golf ball was more amusing and more appropriate for the product than was a female golf ball.

GENERAL AGGRESSION MODEL (GAM)

The *general aggression model* (GAM), proposed in 1995 by Craig Anderson, William Deuser, and Kristina DeNeve, is a general model of aggression that can explain many facets of aggressive behavior. It has been used primarily to understand the effects of media violence on aggression, including such effects among children and adolescents. The GAM incorporates arousal, affect (such as attitudes or aggressive feelings), and cognition (such as beliefs about aggression or aggressive thoughts) into a complex theory of aggression.

The GAM builds on a number of different models of aggression, including theories of priming, cultivation theory, social learning theory, script theory, and theories of arousal such as excitation-transfer theory. Within the model, characteristics of the situation (temperature, violent cues, pain) and the individual (trait aggression, current mood, attitudes) can influence whether or not the person acts aggressively.

The GAM introduces a three-stage process by which situations influence aggressive behavior and affect. In the first stage, situational variables (such as pain, frustration, or depictions of violence) prime aggressive cognitions (e.g., hostile thoughts and memories) and affect (e.g., hostility, anger), which results in increased arousal. In addition, arousal can carry over from other situations to increase an individual's arousal, as predicted by excitation-transfer theory. For example, if an aggressive child is playing a violent video game and becomes frustrated with the game, the child is aroused by that frustration, is probably thinking about aggression because of having punched other characters in the game, and may be in a bad mood because of losing the game.

In the second stage, the primed cognitions and affect, in conjunction with the increased arousal, influence primary appraisals. Primary appraisal involves the automatic or spontaneous interpretation of the situation. To continue our example, if the child is already aroused and in a bad mood because of the game, and then a person accidentally bumps into him or her, the child's mood and aroused state may increase the likelihood of the child's interpreting the bump as intentional. The likelihood of a hostile interpretation of the bump is heightened because the child has recently played the video game, which primed thoughts such as "punching" or "hitting." Given the child's mood, aroused state, and primed cognitions, he or she is likely to spontaneously interpret the bump as an aggressive act by the other person and to respond aggressively. An important component of the model is that arousal, affective feelings, and cognitions can influence each other to heighten the likelihood that the person's primary appraisals will lead to aggressive behavior. In the example, the child's bad mood may make it even more

likely that the aggression-related cognitions will influence how the ambiguous bump is interpreted.

The final stage of the model involves secondary appraisals. These are more effortful appraisals of the situation that involve more thoughtful consideration of various behavioral alternatives to the situation. This final stage can correct or override the spontaneous or primary appraisal that has already occurred. Fortunately, people do not always act aggressively every time they feel like reacting with violence. Factors that influence whether a person is likely to overcome the primary appraisal include how motivated a person is to carefully consider the situation and the time frame in which a person must consider how to act. If a person is rushed or is given little opportunity to consider various responses to a situation, he or she is more likely to respond on the basis of the primary appraisal. But if the person is motivated and has adequate time to consider how to respond, secondary appraisals are more likely to overcome the spontaneous reactions to the bump.

GLOBALIZATION, MEDIA AND

Through the process of globalization, the political, economic, and sociocultural activities of one region of the world can have significant effects on people or communities in regions far away. Today's globalized world is characterized by extensive connectivity and global consciousness. The media play an essential role in globalization and have both positive and negative influences on children and adolescents.

The trend of globalization has led many news organizations to "go global." Global media are usually transnational organizations that generate messages or programs for dissemination to a large number of people around the world, which in turn quickens the globalization process and changes the social environment in which children and adolescents live. Globalization is part of the daily life of youth, affecting their work, leisure, entertainment, language, food, and so forth. In recent decades, technological advancements in cable, satellite, digital media, and the Internet have strengthened the role of the media, particularly the global media, in the globalization process.

The media's importance to globalization can be described in four dimensions that are related to young people's lives: the social, the political, the economic, and the cultural.

THE SOCIAL DIMENSION

Modern media deliver news and messages around the globe, breaking the boundaries of time and place. The global real-time communication system intensifies social interaction over long distances and cultivates the global consciousness of young people. Satellite television and the Internet bring live news and information to young people's doorsteps around the globe. There are few places in the world today where a young person cannot gain access to a continuous flow of information, sound, and pictures from other countries and cultures. The global communication system helps young people reach out to the world and develop multiple understandings about things and issues. Many cultures are now visibly present in the everyday lives of children and adolescents through news channels, movies, comic books, television serials, and advertising. In earlier times, access to foreign media was the privilege of elites, but now most young people can easily gain such access. The lively exchange of cultural and social knowledge broadens young people's minds

and enables them to understand more about the lifestyles, values, and behavioral norms of other countries. Moreover, the global information dissemination network encourages young people to take action from a distance, such as making donations to disaster victims in other countries, showing support for environmental protection, or joining global social movements.

THE POLITICAL DIMENSION

The media provide a sense of global bonding, turning people into "global villagers," or world citizens. Young people can witness an event on television or on online news sites simultaneously at the same time as the rest of the world. They may directly develop views on world issues and reflect on their roles in the global political arena. Young people get together and form transnational communities through online resources such as chat rooms, message boards, and blogs. In the cyber world, many children and adolescents cultivate "cyber friendships" with their online game playmates or global ICQ friends. They can also express opinions on various issues. However, the Internet is also a breeding place of international cyber crime. Children and adolescents may be seduced to commit crime or become victims themselves. Moral education and "global ethics" have been proposed to address these dangers as well as to realize the potential of online relationships among young people educated to become intelligent and responsible global citizens. Global citizenship includes the features of equal rights, global obligations, global participation, and commitment to take active steps to defend the rights of others and promote the common good of the whole global community.

THE ECONOMIC DIMENSION

The media not only play an important part in the globalization of society; they are building their own global business empires. Powerful organizations such as Disney, the News Group, the Hollywood film companies, and international advertising agencies are themselves an expanding world, influencing the development of the overall economy. Multinational corporations and their advertising agencies treat the entire world as a homogeneous market. Children and adolescents are targeted as global consumers. They are encouraged to consume foreign media products and goods promoted by international advertising. Previous studies indicate that the flow of international advertising usually travels from industrial countries to developing nations. In consequence, multinational corporations have large local market shares for various consumer goods in developing countries. The global consumer society provides an opportunity for young people to experience a pluralistic world characterized by different forms of music, films, cuisine, sports, and fashion. However, children and young people are socialized by the media to consume and spend money from a very young age. There is also concern about the overuse of Western signs and symbols in advertising that privilege Western culture over domestic cultures.

THE CULTURAL DIMENSION

There are heated debates about the cultural implications of globalization. Are the media fostering a global society with openness and pluralism, or are they forming a homogeneous global culture? Some globalization scholars point out that the visibility of other cultures within one's own cultural framework makes young people aware that their cultures are no longer given but the result of conscious choice. They can embrace or reject their cultures. The fact that many of the most visible cultural expressions of globalization are American, such as Coca-Cola, McDonalds, Disney, and CNN, leads to concern about Americanization and the erosion of local cultural identity. Research in the cultivation tradition shows that U.S. television content seems to be more important to Australian school children's conceptions of social reality than locally originated programs. However, other studies find that globalization is in fact "glocalization"—a blending of the global with the local. A case study has shown that the globalization of Danish television has not eroded national identity. On the contrary, an increased preoccupation with "Danishness" is reflected in the programming.

The globalization of the media has not given rise to a single global media system. Many scholars observe that there have been both homogenization and heterogenization of communicative spaces. The media, however, play an important role in building a globalized society in which our children and adolescents spend their everyday lives. In some countries, media literacy training is put forward as one of the options to help young people to handle the media in this globalizing world.

H

HEROES, IDENTITY, AND PARASOCIAL INTERACTION

Children today are exposed to a global repertoire of heroes and champions that can be accessed in a multisensorious, almost omnipresent way across a various of media. The heroes seen on television and in computer and online games are part of children's everyday life. The ambivalence of strengths and weaknesses, greatness and littleness, omnipotence and impotence with which heroes are labeled is gaining more and more importance as far as children's social development is concerned. Dieter Czaja even suggests that children need heroes. Children are reported to use these heroes and champions in their own identity formation, especially within the context of their individual, favorite identity themes. Children choose their personal favorites among these heroes and champions and use them in their own identity formation.

The extent to which children apply such parasocially interactive behavior in order to cope with their developmental tasks and everyday experiences depends on their cognitive, emotional, and social development. According to the principles of symbolic interactionism, watching TV is considered an active process of role playing with fictional characters on the screen. Hence, Donald Horton and Robert R. Wohl refer to TV perception as *distanced intimacy*; one must, however, distinguish between this *dissociated intimacy* and the identification that implies a partly subconscious perception and a strong adoption of the actor's role. Children may sometimes act only as observers of the interactions between media characters, yet at other times may allow themselves to be drawn into the events on screen. The latter may lead to an adaptation of the role model in the sense of what Cynthia Hoffner calls *wishful identification*, that is, a strong desire of the child to become like the admired hero—a process that occurs mostly with fiction or fantasy programs—or to what Julie M. Duck refers to as *similarity identification*, which may occur when the child watches programs with realistic content.

Duck shows in her research survey that young children greatly identify with cartoon characters and fantasy superheroes, whereas teenagers tend to model themselves on media celebrities outside their immediate environment (e.g., supermodels, pop stars, film stars, and famous athletes) as well as on "realistic" television characters who are older, more successful, or more popular than they are.

Gender is a major issue here. In general, boys tend to identify themselves with strong male heroes from faraway worlds, whereas girls model themselves after heroines who represent beauty and social virtues. Girls seem to be more "adaptable" in that sometimes they also identify with male characters, whereas boys do not want to—or cannot—orient themselves to female characters. The probability of an identification with a character does not necessarily increase when the child and the media character resemble each other, because wishful identification plays an important role here. The amount of media exposure is also relevant. As early as 1975, Cecilia von Feilitzen and Olga Linne pointed out in their survey that children who watch a lot of television show a stronger tendency to identify with TV characters and heroes than do those who watch less.

Research by Ingrid Paus-Hasebrink (formerly Paus-Haase) shows that TV heroes help children to cope with various role-induced expectations. These heroes provide a virtual space within which children can live out fantasies and desires using characters similar to their own social backgrounds. Children choose from the media according to the individual needs, experiences, desires, and fears that stem from their gender roles and their status in the family. The peer group, as the first group chosen by oneself and relatively uninfluenced by adults, serves the child for the purpose of playful ranking and role modeling. Media favorites can help them adapt to their social surroundings, back a superior status, or make friends with dominant peers. In a friendship, children use knowledge gained from media experiences to create equality and stability. Shared admiration for a media character and the swapping of merchandise toys vouch for mutual affection and create a sense of solidarity.

Preschool children already show significant gender differences in dealing with the media. Boys make use of media heroes to stabilize asymmetric relations—to prevail in their peer groups, friendships, and families, or to help them stand their ground against more dominant peers. Their heroes provide models for fantasies of superiority and protection, and, especially in friendships, they provide a repertoire of behaviors that can be used and tested in concrete situations, for example, when it comes to conflicts with friends. Boys apply these methods to internal and external conflicts. Girls use their media heroines primarily to reinforce a superior position, for example toward their friends or peer group; TV characters also serve as substitutes for lack of social interaction and as an alternative to a reality that seems too narrow from a subjective point of view. TV heroines may also serve as fantasies on which girls project their "helping" and "being saved" visions; such heroines thus allow girls to mentally and actually process their social competence.

Children do not usually immerse themselves in uncritical and unquestioned identification with stars and heroes. In certain social situations (such as having single parents or having unemployed parents), these heroes may become a "sheet anchor" for the identity formation of children. In such cases, children become fans, and there is considerable involvement.

HIP HOP, ETHNICITY RACE IN

Even with hip hop's crossover appeal, it would be difficult to discuss this culture without speaking about the racial dynamics. As producers and consumers of hip hop, the voices of this culture began as those of African American males and still largely belong to them. African American and Puerto Rican voices began the dialogue in the urban ghetto of America in the 1970s. Audiences could see negative images of the black people on the nightly news, and prime-time television shows regulated African Americans to small and stereotypical roles. The music scene offered little relief because many young blacks could not identify with the message of disco music.

In hip hop's early days, racial tension in America was high. African Americans lived in poor urban areas and held little hope for economic advancement. The dominant power structure exacerbated their plight by indirectly blaming them for much of the deviance in society. Hip hop grew out of this oppressive state. Young African American artists (mostly men) used their everyday experiences to let the world know how patriarchal society dealt with minorities. Public Enemy front man Chuck D often refers to rap as "the black man's CNN." Hip hop positioned people of color as commentators on black life.

Scholar Murray Forman argues that rap and hip hop allowed young blacks and Latina/os to contest the dominant discourses about race and class. By focusing on the space where hip hop culture was created, Forman argues that hip hop artists could testify about the black experience. It was a space from which middle-class blacks and most of white America moved away or had never bothered to understand in the first place.

Hip hop helped bring attention to issues of racism. In the 1980s and 1990s, racism and poverty were the subject matter of hip hop culture. As many scholars have argued, hip hop artists became the voice of a generation for many African American males. Andreana Clay studied the influence of hip hop culture on black identity at a youth center in northern California. She found that, even in today's society, where many recognize the social construction of race, black adolescents still use this culture to define their racial identities. In her study involving black and Latina/o teens, she found that, for these teens, their identities are tied to their knowledge of hip hop culture because it is their cultural capital. Being black is synonymous with being engrossed in hip hop culture. The African American teens in the study noted that anyone could listen to or perform as members of hip hop culture, but only African Americans can be authentic members, because of their race. Their views are consistent with Paul Gilroy's scholarship, which suggests that hip hop represents the "blackest" culture.

Political activists, middle-class blacks, and some cultural critics question what happens when young people, media, and society as a whole consider hip hop an accurate representation of the African American race. Black people are not a monolithic group. Indeed, hip hop speaks to a generation of young people, but some suggest that what it says about people of color reifies stereotypical notions on race. As *Essence* writer Joan Morgan notes, rap music videos in particular often show women in subordinate positions. They are, more often than not, merely objects of male desire, willing to do anything to be a part of this culture. More important, these images suggest to young girls that their only asset is their sexuality. These images are detrimental not only to young girls but to young black male fans as well. The images of violence and dominance that are often perpetuated by males in the hip hop community tell young black men that this behavior is acceptable because it brings fame and fortune.

In a study involving African American males and white males, author Fiona Mills found that the white males were titillated by hip hop. They embraced the clothes, the dialect, and the attitude. An important finding in Mills's study with respect to race is that all white males embrace the music but explicitly say that they have no desire to be like its producers. Mills says this distancing illustrates that race plays a key role in how white audiences use hip hop culture. As her subjects told her, they can listen to it but do not identify with the African American community. Furthermore,

her analysis revealed that these white male teens were vehemently against white females showing interest in hip hop or the African American community.

Bakari Kitwana's research provides a stark contrast to Mills's work. His work on white adolescents and hip hop rejects most scholarship that claims that, when white youth listen to hip hop, they are listening without any commitment to improving race relations. He notes that hip hop is just what black and white young people need to maintain a dialogue about racial politics. As the research described in this entry shows, the issue of race in hip hop music has always involved an "us-versus-them" dynamic. In the early days of hip hop, racial segregation may have been necessary, but Kitwana argues that it is not necessary in today's society. In fact, focusing on the black-versus-white battle stifles any progressive thoughts about race.

Kitwana also tries to dispel the myth that hip hop's young fans (black and white) are adopting the stereotypical images in hip hop. He argues that both groups are seeking to make their own declarations about race, not to conform to stereotypes. In much of his research, Kitwana implies that hip hop may provide young people with the political presence that the civil rights movement provided in the 1960s. However, it is hard to ignore the well-founded criticism of hip hop by older African Americans, researchers, and media, which suggests that today's most popular hip hop reifies the stereotypical notions about African Americans that the civil rights generation worked hard to overcome.

HIP HOP, FEMALE PERFORMERS OF

Female artists have been an integral part of the hip hop landscape since its inception. Queen Latifah, MC Lyte, Sister Souljah, Yo-Yo, and Salt-N-Pepa helped redefine the male-dominated genre. Many studies on hip hop and adolescents suggest that, when young hip hop fans see images of women as objects of men's desire and hear hip hop lyrics that are derogatory to women, they incorporate this type of behavior into their social and cultural experiences. On the other hand, some literature suggests that, when female hip hop artists are the creators of the images in music and videos, they reclaim their gender and sexuality. In her study on female hip hop artists, Robin Roberts suggests that, by exercising their power to control their own performance and image, female hip hop performers create an opportunity to fight racism and sexism in patriarchal society.

Through their music, these performers speak about the strength and power of African American women in the history of black struggles. This was a common theme among early female hip hop performers, most of whom were African American. They reminded fans and fellow male hip hop artists alike that female performers have a powerful voice in hip hop music and society.

However, negotiating power within a male-dominated hip hop community is not a simple task. In the 1990s, performances by hip hop artists like Lil' Kim and Foxy Brown suggested that exerting one's sexual prowess is the most lucrative and most feminine way to compete within a genre dominated by males. Much like the blues artists before them, female hip hop artists from the 1990s onward have used sex as a way to reclaim the image of the female body. Scantily clad women are no longer in the background of male hip hop artists' videos. They are front and center in their own videos. Studies of female performers and sexual relationships suggested that female artists illuminating sexual relationships between men and women are illustrating the central power struggle between men and women in society. More specifically, these studies suggest that sex is a powerful resource upon which some female performers draw to construct their sense of self-worth.

In contrast to the "sex is power" theme present in some academic research, researchers such as Polly

McLean and Joan Morgan question how the use of sexuality in hip hop affects the teenage female hip hop fans. More directly, Morgan argues that, when female images are limited to body parts and sexual innuendo, young girls, particularly girls of color, incorporate these notions into their everyday behavior. They become consumed by the notion that women are no more than the sum of their parts, regardless of whether such ideas are promoted by women or men.

HIP HOP, MASCULINITY IN

As a cultural art form, hip hop music burst on the scene in the late 1970s. This unique style of culture and music, which incorporates all forms of rap, became a venue for artists living in urban areas to brag and, more important, to highlight the serious social and economic conditions affecting those living in the low-income areas of America. Since its inception, many researchers have argued that hip hop is predominantly the voice of African American males. Although many white hip hop artists, such as Eminem, have had a profound impact on the genre, and although hip hop fans span the ethnic divide, the most prominent images of hip hop artists are of African American males.

Recent research involving African American and white males argues that males tend to see hip hop as a masculine genre. Fiona Mills's in-depth study on masculinity and rap suggests that rap's hard-core image is what is most attractive to young adolescents. The young men interviewed for Mills's study contend that white adolescents listen to rap because they want other males to perceive them as tough. Young males gravitate to hip hop music in their adolescent years because males dominate it, and the research suggests that some adolescents use the images of hip hop artists to learn about manhood. More specifically, hip hop seems to support traditional notions that, to be masculine, males must reject all things feminine. In fact, a few of the males said that they do not listen to rap music in the presence of females because they consider it a male experience. Furthermore, the males hinted that females could not understand the meaning of hip hop because it excludes female voices and viewpoints.

Many scholars and various child advocacy groups argue that the sex and violence often depicted in hip hop music and videos reify stereotypes suggesting that "real" men must be violent, unemotional, and sexually promiscuous. Early effects studies focused on adolescents' reactions to various elements of hip hop, including nonviolent rap, political rap, or gangsta rap (a form of rap that glorifies thug street life). The manner in which aggression manifests itself in the lives of adolescent males is often the focus of research on hip hop and males. In some cases, the research notes that, when exposed to violent rap music, males tended to accept the use of violence and tended to have a greater probability of committing similar acts.

In addition to aggression, sexual prowess also seems to be a mark of masculinity as portrayed in hip hop. Many studies note that male hip hop artists glamorize their sex lives as a sign of manliness. Masculinity in this arena is defined by the amount of implied sexual activity in the lyrics and music videos. The fact that the focus is on the conquest and not on emotional investment reifies traditional notions both of masculinity in general and of masculinity for black men in particular.

In research involving the responses of Latina/o and African American teens to popular music, Polly McLean studied African American males who were exposed to songs such as 2 Live Crew's "Pop That Coochie," which is replete with sexual innuendoes and images that the teens related to power. A sexual relationship, in their eyes, must depict male domination. They feel that sexual conquests give them status among their male peers and that it is their job as males to initiate sexual acts. A few of the males in the study said that the song made them want to find a girl to have sex with immediately after hearing the song.

It is important to note that the conquests valued by males like those in the study and depicted in hip hop are usually heterosexual. In hip hop, masculinity is often directly related to sexual relationships with women, and men who do not adhere to these gendered scripts are considered weak. Hip hop artists from Ice-T to Eminem write derogatory lyrics about homosexuals. Research examining adolescent males' perceptions of relationships suggests that hip hop artists support their heterosexual cues.

Studies of this nature tend to focus merely on how hip hop contributes to deviant behaviors. Several scholars have argued that effects research, although valid in some instances, is too simplistic. In general, this research shows how adolescents act and react to hip hop at a certain moment in time, but it does not shed light on how these images are incorporated into the everyday lives of hip hop's young audience members.

Scholar Venise Berry's study of low-income adolescents suggests that, for African American males in particular, rap music provides an arena in which they can express their gendered identities. Berry's research involved low-income black youth aged 13 to 18. Berry found that the males in the study could relate to the rappers more because they represented strength and dominance. Because the rappers often spoke of the need to be "hard" to survive in the streets, the males in Berry's study could relate to that lifestyle as their reality. Rappers made it okay to be who they were. Another interesting finding in Berry's study, which is consistent with other studies of males and rap music, is the use of the "cool pose," which can be as simple as crossing one's arms or as complicated as displaying gang signs. Regardless of the gesturing, researchers argue that this simple act reflects an image of control and, in some cases, defiance.

Many researchers would argue that hip hop music itself focuses on defying traditional notions of gender, age, and race. Therefore, more studies should examine adolescents' understandings of these interlocking notions as they relate to hip hop.

HIP HOP, PORTRAYALS OF WOMEN IN

Hip hop artists, fans, parents, and scholars have debated the genre's impact on children since the music hit the urban streets of New York City in the 1970s. Hip hop culture, of which rap music is the most dominant part, became a voice for artists such as Grandmaster Flash, Chuck D, and Public Enemy. Today, hip hop is one of the most controversial, yet influential, musical genres. Hip hop tends to be the voice of urban males. Hip hop artists' songs and videos tend to show life from a male, often African American, perspective. Consequently, one of the most common criticisms focuses on the frequent negative portrayals of women in hip hop music and videos.

Male hip hop performers often refer to women in their lyrics and music videos as "bitches" and "hos." Women also are often portrayed as the targets of violence or degrading sexual acts. Because women are often in subordinate positions in hip hop music, many researchers question whether these representations contribute to adolescents' understanding of gender politics. Research on adolescent males suggests that, when exposed to violent hip hop music, males tend to subscribe to the notion that they must use violence to control women.

In their study on rap music and teen dating, violence researchers James Johnson, Mike Adams, Leslie Ashburn, and William Reed showed male and female teens violent and nonviolent rap videos and studied the effects of this exposure. They found that females who are exposed to rap music that depicts women in subordinate roles are more likely to accept teen dating violence. For males, the level of acceptance did not have a direct correlation to exposure to rap videos.

Many of the early studies focusing on the effects of rap music on adolescent behavior have drawn criticism from cultural researchers for focusing too much on the most controversial aspects of hip hop. Scholar bell hooks agrees that young hip hop audiences are exposed to negative portrayals of women but argues that these images reflects the sexism and misogyny that exists in American culture as a whole.

With respect to adolescent girls, feminist researcher Joan Morgan argues that there is no sense of "self" within hip hop music videos, particularly for African American adolescent girls. The images in rap music videos present black women as no more than the sum of their parts. She notes that the mainstream popularity of Lil' Kim and Foxy Brown help to propel the materialistic nature of sexuality in rap music videos. Morgan also notes that, when young African American girls see these images presented by economically successful black women, they get a false sense of what it means to be female and what it takes to have a successful romantic relationship. Furthermore, Morgan argues, these videos have adopted mainstream values for women that give priority to thinness and light skin.

Female rappers were present during the early days of hip hop and are also questioning female representation within this genre. They have had a presence within this male-dominated landscape since the 1980s. Female hip hop performers argue that the portrayals of women in hip hop music and videos are hurtful and misguided. Many studies have focused on how female artists have reclaimed the images of the hypersexual and defenseless female from male hip hop artists. Artists such as Queen Latifah and MC Lyte have countered these images and have attempted to show that portrayals of scantily clad, subordinate females are no longer acceptable. In contrast, artists such as Lil' Kim and Foxy Brown go even further and exploit such images by selling their own sexuality.

A recent study involving 60 Latina/o and African American males and females found that Latinas and African American females feel embarrassed and defensive when it comes to the depiction of women in hip hop lyrics and videos. The researchers asked the girls and their male counterparts to listen to several different types of music and then respond to a series of questions about the content of the music. Responses from the girls indicate that they were ashamed of the way men treated women in hip hop music and videos, but they were also angered by the fact that the women in the videos allowed themselves to be depicted in that manner. They also noted that they often have to defend themselves against these stereotypical images to mainstream society. However, the males in the study remained detached from the negative images of the females in the videos, arguing that, in some instances, they depict the reality of some male-female relationships.

Although media scholars and parents have been criticized for their focus on the stereotypical portrayals of women in hip hop music and videos, continued exploration of the portrayal of women in hip hop—particularly as seen through the eyes of adolescents—would provide further insight into how this genre affects their everyday lives.

HIP HOP, VIOLENCE IN

In the 1970s, as disco ruled the mainstream airwaves, music artists in the urban ghettos of America were creating a sound and a culture that would be around

for several decades. Hip hop culture encompasses elements such as rap, break dancing, and graffiti. Academics and parents have spent decades trying to understand the appeal of this culture to young people. In the early days, young African Americans embraced hip hop culture as a way to reject a racist power structure. Today, hip hop culture's influence expands beyond any race or geographic border. However, its producers and the images are still largely African American. Much research has examined the impact of hip hop culture, of which rap is a central component, on violence in society in general and on young people in particular. Early research on the genre seemed to suggest that rap music helped to glorify violence.

As a culture, hip hop encompasses several forms of rap music, gesture, and attitude. "Gangsta" rap, or hard-core rap, seems to be at the center of much criticism. For decades, researchers have explored the effects of rap music on adolescent behavior. In one of the early studies on rap music and teen dating violence, James Johnson, Michael Adams, Leslie Ashburn, and William Reed discovered that adolescents accepted violent behavior after being exposed to rap videos depicting violence. The researchers interviewed 60 African American males and females aged 11 to 16. In the study, the researchers exposed the participants to violent and nonviolent rap videos. They then asked the adolescents to provide their reactions to a story about teenage dating violence. The most significant finding of this study is that the girls who were exposed to violent rap music videos tended to be more accepting of violent behavior in relationships. The results of the study suggest that exposure to rap videos did not change African American males' acceptance of violence in relationships. The researchers suggested that this might be a result of their prior attitudes toward teen dating violence. Although these studies illustrated the need to examine the effect of exposure to rap music on young people, they failed to put it in a broader context.

Many researchers note that the violence in some elements of hip hop culture cannot be ignored, but they question whether demonizing the producers of the genre is the solution. Scholars such as Michael Eric Dyson argue that focusing on the negative aspects of any genre is too simplistic. He acknowledges that rap music can be violent and sexist. However, he, like scholars such as bell hooks, argues that the violence illustrated in rap music is indicative of the violence in society as a whole. No one musical genre or culture can be responsible for the excessive violence in America. Furthermore, the attention that media and some scholars pay to the violent nature of rap leaves the dominant power structure unaccountable for the violence in society. Scholar Tricia Rose echoes this sentiment. In her research on rap music, she addresses public's obsession with rap-related violence. She argues that media and scholars continue the social discourse that posits young African Americans as social deviants.

In their study of black youth violence, Jabari Mahiri and Erin Conner used 41 middle school students to determine how young people interpret certain elements of popular culture. All the students were from a charter middle school in a low-income section of a city in California. During the research, the students were asked about their personal experiences with violence and their perceptions of hip hop's representations of violence, crime, and sex. The results of the study show that the adolescents rejected the argument that rap music helps to perpetuate violence. Because of their everyday experiences, these adolescents argued that rap music is not the cause of violence. In fact, they, like many scholars, argued that the violent nature of rap music is symptomatic of a much larger problem in society. Another key finding of this study is the fact that the students used the violent images of rap and media's constant focus on these images to try to eradicate violence in their communities. In an effort to combat the media images that present them as "violent others," these young people began to change their behaviors. Instead of reifying the images that suggest that they must be violent to survive, the adolescents in the study said that they challenged these images by seeking help from adults before resorting to violence.

Other members of the African American community, from scholars to church leaders, are searching for ways to combat the negative images in hip hop. Many of them, such as Spelman College's Zenobia Hikes, suggest that the music once used by rappers as social protest has turned into a hypercriminalized entertainment genre. Young people are often hurt the most by these images because they cannot distinguish reality from fiction. They believe that violence and hypersexualized behavior are the keys to success for African Americans. Hikes suggests that young black females see these images and believe that being

objectified is the only choice they have in life. The black males see these images and believe that they have to be violent and sexist to be considered "real" black men.

Hikes and *Essence* magazine suggest that the only way to combat these images is to empower young women and men to question those stereotypes that seek to confine them, regardless of the perpetrators of such images. *Essence* magazine sponsored a yearlong campaign called Take Back the Music, which created a space for rappers, music industry professionals, and the African American community to have an open dialogue about the negative portrayals of black life within the hip hop community. They encouraged the creators of these negative images to take accountability for their actions. They encouraged their readers to reject these images by fighting back where it counts: with their dollars.

HIP HOP, YOUTH CULTURE AND

Youth cultures are often seen as moments of rebellion for adolescents—moments or movements that allow young people to distance themselves from the adult power structures that seek to confine them. Music is at the center of many youth cultures. From 1960s rock to punk to the rave scene, young people use music to carve out their places in society. For adolescents, this collective bond is much bigger than just the music. The music helps to create a culture that tells young people that who they are is acceptable. Since the 1990s, the music and culture that are the voice of a generation is referred to by many as *hip hop*. Scholars who study hip hop often use the term to refer to the culture, its music, and its attitude.

Scholars trace hip hop's roots back to the late 1970s. However, as most scholars argue, hip hop gained its prominence in the 1980s as it became the voice of African American struggles in urban cities during the Reagan administration. As young people in urban ghettos fought to deal with poor economic conditions and racism, artists such as Grandmaster Flash and Gil Scott-Heron gave them an outlet to voice their daily struggles to the world. Scholar Craig Watkins notes that youth cultures such as hip hop are particularly relevant to black youth. In his research, he argues that black youth use hip hop to reclaim and recreate society's images of them. Unlike other Generation X cultures that focus on mostly Euro-American styles, hip hop illuminates the voices of black youth.

Early research on hip hop and youth culture seemed to highlight its positive influence on African American youth in particular. As Carl S. Taylor and Virgil Taylor note, hip hop became a genre with which African American young people could identify because it allowed them to be "real" and to fight against a dominant ideology they believed to be intolerant and hypocritical. Researchers Douglas Kellner and Katina Stapleton suggest that rappers articulate the experiences in their communities and call for collective action to find possible solutions to problems such as violence and drug use. Stapleton notes that rap music provides an arena for pragmatic political action and illustrates how members of the hip hop community take action against hegemonic ideas about the urban experience.

In her 2003 study, *Keepin' Real*, Andreana Clay examines the specific relationship between black youth and hip hop culture. Her research focused on a group of African American young people at a city youth center. Clay found that, for these African American adolescents, an understanding of the hip hop culture is essential to navigate within their social worlds. It is, as Clay notes, their cultural capital. The adolescents use fashion, gestures, and language to gain and maintain their black identity within hip hop culture.

The challenge to authority in general, which often unites members of this youth culture, is also what draws the most criticism from media, academics, and parents alike. Images and lyrics promoting violence toward members of authority and other rappers are passed along as "cool" or "hard" ways to live. Furthermore, as many researchers studying the treatment of women, particularly black women, have noted, violence and sexual degradation are common themes among some artists within hip hop. These images are not hidden; they are blatant portrayals that young people not only see but incorporate into their everyday lives.

Researchers note that, for female fans in particular, these images may have a more devastating affect. Spelman College's Zenobia Hikes contends that images of women in hip hop are often restricted to body parts. Young African American girls see these images presented by male rappers and some female rappers and get a false sense of what it takes to be successful. Female artists such as Lil' Kim are notorious for promoting the "sex is power" image in their songs and videos. African American girls are inundated with images of women that focus on every body part but never on their intellectual abilities.

Hip hop as a culture may have its roots in African American culture, but its appeal reaches beyond the African American community. Many scholars note that suburban white adolescents also listen to this music and become active negotiators within this culture. White rappers such as Marshall Mathers, aka Eminem, exploded onto the hip hop scene in the 1990s. Even before rappers like Eminem, this culture seemed to give white youth a chance to use the music as a way to rebel against their parents and various school administrators. Furthermore, Eminem presented an image of the angry white male that many young people felt society ignored. In his book on white kids and hip hop, author Bakari Kitwana suggests that white young people's interest in hip hop does not stifle its message about racial inequality. In fact, he argues, it helps to cut down racial barriers—the more young people are exposed to the message of some rap music, the more they try to understand the complex nature of life for minorities. Kitwana interviewed more than 100 white teenagers and found that hip hop connects this generation much as other music genres did. It allows the young people to challenge the rhetoric of adulthood.

Although hip hop crosses cultures, the relationship within this youth culture has not always been harmonious. Young hip hop fans are by no means a monolithic group. The struggles between white and black youth are real. Past research on black youth and hip hop suggest that black youth are suspicious of those outside of African American community who adopt the style and attitude of hip hop. They suggest that white people are "passing" for black. In other words, white youth can adopt the attitude without adopting any of the "real" pressures of being a member of a minority group in society. Fiona Mills also found that white adolescents feel the same way. In fact, in her interviews with several white hip hop fans, the teens expressed how in tune white adolescents are with the concept of voyeurism. In their everyday lives, her subjects made it a point to distance themselves from the lifestyles perpetuated in rap music and the African American community in general.

HIV/AIDS, MEDIA PREVENTION PROGRAMS AND

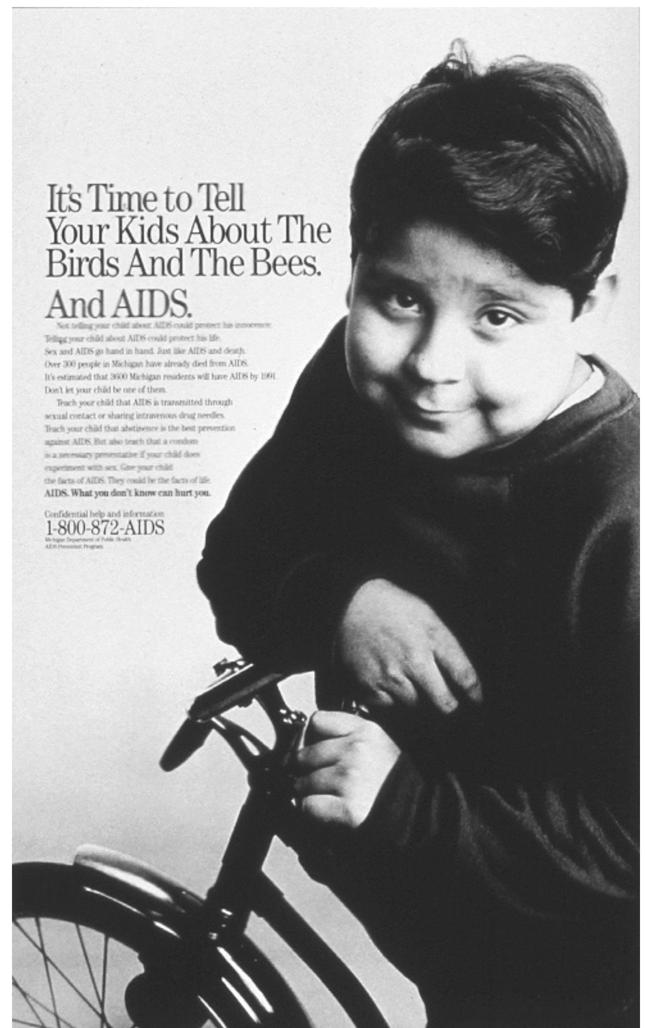
Since HIV/AIDS was first recognized as a public health problem, a variety of approaches have been used to inform the public about HIV risk and prevention. Recognizing that the mass media are integral components of prevention programs, educators, health practitioners, media researchers, and others have recommended the use of media-based prevention efforts. In response to such recommendations, media campaigns have been developed, and local communities have often been saturated with HIV/AIDS prevention messages. Children and adolescents need HIV/AIDS prevention messages that are developed specifically for them, and media-based projects have attempted to fill this need by providing age-appropriate HIV/AIDS information.

One of the first media-based HIV prevention campaigns, America Responds to AIDS, was developed under the auspices of the Centers for Disease Control and Prevention (CDC). The foundation of this campaign was a series of televised public service announcements (PSAs) that promoted healthy sexual behavior and awareness about HIV/AIDS.

After linking health communication to HIV/AIDS prevention, health practitioners soon realized that prevention efforts needed to be culturally and developmentally specific. Thus, prevention programs have been geared toward specific cultural and developmental groups, including children and adolescents.

One might wonder about the need for HIV prevention programs directed toward these groups, as children and adolescents generally represent fewer than 2% of the documented cases of HIV/AIDS. However, the need for HIV/AIDS preventative information targeted to these groups is evidenced in research showing that (a) the electronic media are a source of AIDS information; (b) elementary school children have reported on the AIDS Survey for Kids that they believe they are at risk of contracting AIDS; (c) adolescents, in particular, are at high risk for contracting HIV infection in that approximately half of a nationally representative sample of high school students reported having engaged in sexual intercourse, and nearly 7% had initiated sexual intercourse before age 13 (CDC, 2002); and (d) many do not use condoms for protection against sexually transmitted diseases, including HIV/AIDS.

In response to this need, a number of media-based HIV/AIDS interventions have been developed that are geared specifically to children and adolescents. A decade ago, in 1996, Snyder identified more than 80 studies of such interventions.



HIV/AIDS posters in the late 1980s and early 1990s often used photographic images to target specific racial and ethnic groups and to dispel myths about at-risk populations. This poster from the AIDS Prevention Program of the Michigan Department of Public Health, with its picture of an attentive child, was part of a campaign suggesting to parents that they have a responsibility to educate their children about HIV/AIDS.

Although video is the most commonly used format, these interventions have used a variety of channels, including pamphlets, video games, documentaries, Internet websites, TV shows, film, popular music, radio, posters, comic books, and rap music. Featuring messages about condom use, safer sex, and abstinence, in language that young people understand, the interventions attempt to

- Increase awareness of the importance of preventing HIV infection
- Increase the use of condoms and reduce unprotected sex
- Increase the perceived personal vulnerability to contracting HIV infection
- Increase awareness of how to get tested for HIV/AIDS

Many local, regional, and national organizations have been involved in HIV/AIDS prevention. As an example, CDC has continued its initial involvement in HIV/AIDS prevention with several media-based projects, including (a) *Respect Yourself, Protect Yourself,* which is targeted toward people 18 to 25 years old and features a series of radio and television spots showing young people discussing and modeling protective sexual behavior; (b) *Street Smart,* a skills-building program designed to reduce HIV risk among runaway and homeless youths, which uses media developed by the participants themselves; and (c) *PROMISE* (Peers Reaching Out and Modeling Intervention Strategies for HIV/AIDS Risk Reduction in their Community), which is a community-level HIV prevention intervention that relies on role-model stories and peers from the community. The CDC also sponsors a hotline that offers referrals and resources on HIV/AIDS—the National Prevention Information Network (NPIN).

One private sector organization, the Kaiser Family Foundation, has assumed a monumental role in HIV/AIDS prevention among young people both nationally and internationally. Since 1997, Kaiser has partnered with media organizations to produce and promote HIV/AIDS messages geared to adolescents and young adults. The following are four public education campaigns currently sponsored by the Kaiser Family Foundation and Viacom entities:

1. *Univision: iEnterate!iProtegete!* Univision's iEnterate!iProtegete! (Get Informed/Protect Yourself) campaign was launched in 2001 as a partnership between the Kaiser Family Foundation and Univision, the leading Spanish-language television network. Targeted toward young Latina/os, the campaign provides free Web-based resources and print materials on HIV/AIDS, sexually transmitted diseases, and related issues.

2. *MTV–think.* Designed as a sex education tool for young people, MTV's *think* campaign provides website users with information about HIV/AIDS and other STDs. It also provides referrals to counselors and local HIV/AIDS testing centers. It is estimated that this campaign has distributed close to a half million copies of a pamphlet entitled "It's Your (Sex) Life: Your Guide to Safe and Responsible Sex."

3. *BET: Rap It Up.* The partnership of BET's Rap It Up, between Black Entertainment Television and the Kaiser Family Foundation campaign, is the largest public education effort on HIV/AIDS directed specifically to African Americans. Launched in 1998, *Rap It Up* was designed to educate network viewers about HIV/AIDS and to encourage African Americans to get tested. The partnership includes special programming, public service announcements, online content on bet.com, and a free resource and referral service.

4. *Viacom: KNOW HIV/AIDS.* The Viacom KNOW HIV/AIDS campaign comprises television, radio, and outdoor PSAs and other programming that encourages young people to get tested for HIV. It also includes programming specifically directed to African Americans. Messages focus on asking those at risk to "know" their status. This campaign recently launched an online marketing effort, www.spreadtheknow.com, which features various interactive content. One component of the Viacom-Kaiser Family Foundation partnership involves incorporating HIV/AIDS messages in television shows and movies produced by Viacom companies or broadcast on Viacom-owned networks, such as CBS, UPN, MTV, and BET, among others.

Some of the media-based projects developed for children and adolescents have been successful, especially when such efforts were accompanied by other interventions such as school-based efforts. The consensus is that these programs have been highly effective in increasing knowledge about AIDS. For example, the Kaiser Family Foundation

estimates that millions of people have been exposed to information about HIV/AIDS and related issues through its media-based efforts.

Media-based interventions have been less effective in altering beliefs, attitudes, and behaviors. For example, in reporting on the effectiveness of the Family/Media AIDS Prevention Project in 1994, R. A. Winett and E. S. Anderson noted that an increase in parents' and teens' knowledge about HIV/AIDS was not followed by a concomitant increase in teens' HIV/AIDS risk-reduction skills. Furthermore, reviews of media-based interventions generally indicate that such interventions have had small positive effects on adolescent attitudes and behaviors related to HIV/AIDS prevention and the practice of safer sex.

The quality of evaluation of these programs has not reached a state-of-the-art level, and additional research is needed to identify the effectiveness of media-based HIV/AIDS interventions. However, it is expected that evaluations will improve, that the successes noted here will be replicated and expanded, and that media-based prevention strategies will continue to be implemented in programs designed to prevent HIV/AIDS in children and adolescents.

HORROR FILMS

Why do so many of us enjoy being told scary, frightening stories? What are some of the consequences of such exposure? In light of the continued popularity and profitability of horror films over the past four decades, these questions have become the focus of

growing public debate and scholarly attention. Research in the past two decades has examined the role of gender on the viewing experiences of young men and women; more recently, children's fear reactions to horror films have been analyzed.

Horror films first appeared during the silent film era. *The Cabinet of Dr. Caligari* (1919) is generally recognized as the first production of this genre. The period from 1920 through 1960 was dominated by gothic horror films, in which a sense of eeriness was created with tilted cameras, strange buildings, and shadowy, often exotic characters. Films of this period were often highly derivative and usually avoided depictions of dismemberment and blood because of strictly enforced film production codes. Horror films that exploited the inventive use of special effects to portray grisly slaughter first appeared in the 1960s. These gory productions typically pushed the limits of realistically gruesome imagery.

Horror movies that frequently juxtaposed erotic and violent imagery, commonly referred to as *slasher films*, dominated theaters beginning in the 1980s. The combination of violence and attractive girls was popular at the box office, and three of the most successful horror movie franchises (*Friday the 13th, Halloween, Nightmare on Elm Street*) emerged during this period. However, apparently in response to critical concerns about potential consequences of mixing erotic and violent images, a clear shift in content is evident in contemporary horror films. For example, Barry Sapolsky, Fred Molitor, and Sarah Luque report that, compared with those of the previous decade, horror films during the 1990s escalated the projection of graphic violence while essentially eliminating erotic imagery.

The horror film, which was long the purview of independent producers, has become a priority for major film studios. The ultimate goal of a major studio is the discovery and development of a long-term horror film franchise—such as *Friday the 13th*, *Halloween*, *Nightmare on Elm Street*, or *Scream*—that will generate large profits from both story concept serialization and the sale of residual products (e.g., books, costumes, games). However, as T. L. Stanley makes clear, tremendous profits are typically enjoyed by almost all contemporary horror films. Isolating four recent films (*The Blair Witch Project*, *The Grudge*, *The Ring*, and *Saw*), Stanley outlines the huge discrepancy between the average production cost of $14.8 million and the more than $188.2 million in combined worldwide gross income.

Horror films are especially appealing to avid moviegoers—individuals who see at least 12 films per year and account for 77% of all theatre admissions, and who typically are single, well-educated, 16-to-20-year-olds from middle-class, urban families—and this emerges as a key reason for the continued success of such films. Equally important, however, is the fact that horror audiences typically are split almost evenly between male and female viewers, with many reporting a strong interest in the communal experience of being scared with their friends. In other words, horror films are, for many viewers, great "date movies."

This phenomenon was first observed and researched by Dolf Zillmann and his colleagues, who demonstrated in an experiment that an opposite-gender companion's affective reactions to horror strongly impacted a coviewer's experience of distress, delight, and attraction. Specifically, young men and women were exposed to a horror film in the presence of a same-age, opposite-gender companion who expressed mastery, affective indifference, or distress. It was found that men enjoyed the movie most in the company of a distressed woman and least in the company of a mastering woman. Women, in contrast, enjoyed the horror film most in the company of a mastering man and least in the company of a distressed man. Further, men who displayed mastery and women who displayed distress enjoyed an enhancement of their physical appeal. Building from these findings, Zillmann and James Weaver advanced the *gender-socialization theory* of reactions to horror, also referred to as the *snuggle theory of horror*, explicating some of the social motives for and social consequences of the consumption of cinematic horror. Richard Harris and his colleagues have reported fascinating evidence supporting this theory.

Obviously, not all consequences of horror film viewing are positive, especially when children watch such materials at a developmentally premature stage. Joanne Cantor illustrates many of these concerns summarizing her program of research on fear reactions.

HUMAN-COMPUTER INTERACTION (HCI)

Human-computer interaction is a thriving field of study of the interaction between humans and computers, with a focus on applying knowledge of human use of interactive communication technologies to the design and deployment of such systems. Interaction design, or the structuring of the flow of communication between the user and the system, involves users in the design process. With the development of new educational tools, electronic game toys, online sites and navigational tools, and filters, children and adolescents have become the focus of computer interaction design both as co-creators and as end users.

HCI draws from a number of academic disciplines, such as computer science, cognitive psychology, sociology, mass communications, anthropology, ergonomics, business, and industrial design. According to the Association for Computing Machinery–Special Interest Group on Computer-Human Interaction (ACM SIGCHI), which is a leading international society for professionals, academics, and students interested in human-computer interaction, HCI research in the field of computer science focuses on the engineering of human interfaces, whereas HCI research in cognitive psychology is concerned about the user's mental processes and the analysis of human user behavior. Similarly, whereas the field of industrial design focuses on the design of interactive interfaces and the usability of such interfaces, technology research in the fields of communication and media studies primarily investigates the ways in which human users communicate with each other with the help of such technologies, both interpersonally and in mass-mediated ways.

THE HUMAN

Communication researchers such as S. Shyam Sundar of Pennsylvania State University and Clifford Nass of Stanford University focus on the nature of users' orientation toward computers and other media technologies—as either independent sources of information or simply mediums between sources and receivers. Under the former conceptualization, the degree to which individuals treat computers as human is an indication of their tendency to view them as autonomous sources. Several experimental studies in the media equation literature document the human tendency to apply rules of human-human interaction to human-computer interaction. For example, research by Byron Reeves and Clifford Nass has shown that we apply politeness norms and gender stereotypes to computers, respond to them as if they had humanlike personality traits such as dominance and submissiveness, and otherwise treat them socially by applying rules pertaining to self-other praise-criticism, self-disclosure reciprocity, and behavioral consistency, among a host of other domains. Research on such social attributions by Clifford Nass and Youngme Moon also suggests that these social attributions arise not from a conscious decision to anthropomorphize computers but rather from an automatic tendency to

apply rules of human-human interaction without being mindful of the fact that one is interacting with a nonhuman entity.

In fact, the socialness of human-computer interaction has been a fundamental preoccupation in this subfield. For example, an entire design movement, labeled *social computing,* is devoted to research and development of interfaces that contribute to compelling and effective social interactions. Emphasis is placed on research related to the social relationships in which users engage with computers and other users via computers when they are online. In his 1994 article "Social Computing," Doug Schuler has described social computing in terms of software that functions as an intermediate entity in any social interaction. The relationship between social behaviors and interactions with computing technologies has been the focus of research done by Christopher Dryer and colleagues. Another distinctive aspect of social computing is highlighted by some researchers at the IBM Research Division. John Thomas and colleagues emphasize the role of digital systems that can draw upon social information and context. According to these researchers, such social computing enhances the activity and performance of people, organizations, and systems. On a similar note, Adrian Cheok and colleagues call attention to the social, cultural, organizational, and interactional context that social computing brings to mixed-reality environments, which, they argue, is crucial for embodiment in such environments. Microsoft Corporation even has a social computing group, which, according to their website, is devoted to "developing software that contributes to compelling and effective social interactions, with a focus on user-centered design processes and rapid prototyping" ("Microsoft Research Areas," para. 9).

THE COMPUTER

For HCI scholar John Carroll and most computer scientists, human-computer interaction (also termed *computer-human interaction,* or CHI) is essentially a determination of usability. They argue that understanding and creating interfaces that are usable should be the primary focus of study. The strength of the interactive computing systems they build is assessed by implementing them among users and gauging their functioning along a set of measurable criteria.

The business perspective on human-computer interaction is summed up nicely by Gitte Lindgaard and Nicola Millard. For them, the value of good HCI rests in improved customer satisfaction and more positive brand image, which is achieved by systems that generate profit and value by increasing productivity.

THE INTERACTION

Researchers in the area of persuasive technology are more interested in the actual interaction between a human user and the computer, and they build and study technologies the fundamental goal of which is to change the attitudes and behavior of users. In the context of customization of new communication technologies, Marko Turpeinen and Timo Saari draw attention to the significance of customization of information based on its emotional and cognitive effects on different users of communication technologies.

Co-adaptability is another aspect of the interaction highlighted by anthropologists such as Wendy Mackay. Her primary claim is that an interaction between a technology and a human is co-adaptive, and users not only adapt to the available technology but also modify it to fit their needs. Study of HCI with this focus, then, is undertaken with the belief that the environment and human behavior affect each other mutually. Resistance to new technology is another aspect of human-computer interaction studied by some researchers in the field of management information systems (MIS), a field parallel to HCI. Scholars like Ping Zhang and Andrew Dillon have pointed out that HCI and MIS share the research goals of increased and practical understanding of the best use of information technology to suit user and organizational needs. The major areas of research in this field are user attitudes, perceptions, and acceptance and use of information technology.

HCI AND CHILDREN

Lately, children have become an integral part of interaction design. To begin with, children and adolescents are now routinely used in usability testing, and their input is taken very seriously. Libby Hanna, Kristen Risden, and Kristin Alexander of Microsoft Corporation were among the first to recognize the unique interaction styles of children when they developed guidelines especially geared to adapting test procedures to maximize the use of children in lab-based usability studies. They catalogued the likes, dislikes, and capabilities of preschool, elementary school, and middle school children and

proposed specific guidelines about setup and planning, introduction, and interaction with children both during and after the test.

More recently, children have been recruited by Allison Druin and her Human-Computer Interaction Lab team at the University of Maryland for partnering in cooperative or participatory design involving collaborative inquiry as well as immersion in technology. This unique technology design team includes seven children (ages 7 to 11) along with researchers from various fields, such as computer science, education, art, robotics, and other disciplines. According to their website, they are an "intergenerational, interdisciplinary team" that "pursues projects, writes papers, and creates new technologies" ("Children as Design Partners," para. 1). According to Mona Leigh Guha and colleagues, this is emblematic of a new movement or research area called *interaction design and children (IDC)*, which involves techniques such as "mixing ideas" to foster design innovation.

As Amy Bruckman and Alisa Bandlow of Georgia Institute of Technology point out, HCI research involving technologies for children can be classified according to the function or desired outcome, such as entertainment and education, each with its own criteria for judging efficacy. However, they argue that, with the arrival of the Internet, newer functions have become prominent, such as online collaborative learning and the need to shield children from unsafe and age-inappropriate content.

HCI AND ADOLESCENTS

Adolescents' computer use and its effect on their skills, development, and social relationships have also been a significant part of research in the HCI field. Research done by Myron Orleans and Margaret Laney found gender differences in the effects of computer use on the social life of adolescents. Specifically, they found that boys are more likely to socialize around the computer, whereas girls are more likely to do their computer work without compromising their sociality. The use of the computer by adolescents and its effects on their development are discussed in their extensive review of the literature by Kaveri Subrahmanyam, Patricia Greenfield, and Elisheva Gross of California State University, Los Angeles, along with Robert Kraut of Carnegie Mellon University. Their focus of research is excessive computer and Internet use and its effects on adolescents' loneliness, social relationships, and psychological well-being. Research involving devices such as instant messaging and computer games have largely allayed concerns about the promotion of dysfunctional social relationships by the new medium. For example, Rebecca Grinter and Leysia Palen note that informal talk, or socializing, is one of three primary activities that characterize teenage IM communications (the other two are event planning and schoolwork collaboration).

Research on gaming has also been a significant contributor to the HCI literature. Kevin Durkin and Bonnie Barber conducted an exhaustive survey of the literature and came away with the conclusion that computer game play does not have the negative effects attributed to it anecdotally. If anything, they found positive associations with game play. In their own study, they found that optimal levels of game play (compared to no play) were associated with such positive psychological attributes as family closeness, physical activity, attachment to school, school attendance, favorable mental health, and lower substance use. They concluded that computer games, when qualified by these aforementioned conditions, are a positive attribute of youth, even though evidence of negative effects exists in the literature. Judy Robertson and Judith Good have pioneered the use of computer-game authoring in order to develop adolescents' story-narration skills. Their approach goes beyond simply encouraging youngsters to play age-appropriate games (which by itself is quite educational) and enables children and adolescents, via specially designed workshops, to create their own computer role-play games for use by friends and family. The goal is to provide an opportunity for young people to tell stories through the emergent medium of computer games. In evaluating their Game Maker workshop, the researchers found that 12-to-15-year-olds enjoyed the experience and considered it quite engaging and rewarding. Encouraged by its motivational advantages, Robertson and Good recommend using computer-game authoring in the classroom to raise literacy as well as narrative abilities.

Research on usability testing with teenagers has also yielded remarkable results. Carolyn Milligan and Max Murdock of Iomega provided kids with drive installation kits, then observed mistakes and problems encountered by them in order to design child-friendly software. According to these researchers, teens represent the increasing number of mass-market consumers who are novices at using technology and who prove a

rich resource pool for research because they have grown up with computer technology, they have a mindset of invincibility about computers, they lack the biases of most professionals, and hence they are open, honest, and have a unique approach to technology use, including anthropomorphic interactions with machines. Milligan and Murdock use the term *GUI (Graphical User Interface) bloomers* for such teenagers, to point out that these children have had the unique experience of growing up with computers when the computer technology was growing up with them at the same time.

I

IMAGINATION, EFFECTS OF TELEVISION ON

The question of whether and how television viewing impacts children's imagination has been debated since the medium became part of everyday life, and there is still no consensus on this issue. On the one hand, television viewing is believed to produce a passive intellect and to reduce imaginative capacities. On the other hand, there has been enthusiasm about educational television viewing fostering children's imaginative skills. This entry reviews the existing research on television's effects on children's imagination and evaluates four hypotheses on the impact of television on imagination that have been proposed in the literature.

Researchers have advanced contradictory opinions about the influence of television on imaginative play and creativity. Some authors believe that television stimulates play and creativity. Many others, however, argue that television hinders imaginative play and creativity. A stimulation hypothesis and three important reduction hypotheses are discussed following.

Before reviewing the literature, it is necessary to define two aspects of children's imagination that have been addressed in earlier studies: *imaginative play* and *creativity*. In imaginative play, children pretend that they are someone else, that an object represents something else, or that they are in a different place and time. Creativity is children's capacity to generate many novel or unusual ideas, for example, in drawings or stories.

Children's imaginative play is usually measured by observing children when they are playing, either alone or with other children. Children's creativity is measured in different ways. Experimental studies often use measures related to the media to which children are exposed. For example, children are asked to invent problem solutions, to make up a story, or to make a drawing based on the stimulus medium. Correlational studies have often used divergent thinking tests as a measure of creativity. A divergent thinking test requires that the child come up with as many solutions as possible to some open-ended problem. An example of such a problem is, "How many uses can you think of for a shoe?" and "Just suppose you hung on the clouds; what would happen?"

THE STIMULATION HYPOTHESIS

According to the stimulation hypothesis, television enriches the store of ideas from which children can draw when engaged in imaginative play or creative tasks. Adherents of this hypothesis argue that television characters and events are picked up, transformed, and incorporated in children's play and creative products and that, as a result, the quality and quantity of their play and creative products are improved.

There is indeed evidence to suggest that children use television content in their imaginative play and creative products—their stories, their songs, their dances, their drawings. A 1981 study by M. M. Vibbert and L. K. Meringoff showed, for example, that an audiovisual film elicited drawings based on pictures in the film. However, this does not necessarily mean that children's television-related play or creative products are more creative. There is as yet no evidence that the quality or quantity of imaginative play or creative products is improved through television viewing in

general. More specifically, none of the existing studies has as yet demonstrated that overall television viewing is positively related to imaginative play or creativity.

Although a stimulating effect does not appear to be true of television viewing in general, it has been suggested that educational viewing might stimulate children's imagination. Two studies, one by Jerome and Dorothy Singer and the other by Daniel Anderson and his colleagues, have shown that educational children's programs such as *Mr. Rogers' Neighborhood* and *Sesame Street* can promote imaginative play and creativity in both the short term and the longer term.

THE PASSIVITY HYPOTHESIS

Adherents of the passivity hypothesis see television as an "easy" medium, requiring little mental effort. With a minimum of mental effort, the child viewer consumes fantasies produced by others. According to the passivity hypothesis, this leads to a passive "let you entertain me" attitude that undermines children's willingness to use their own imagination in play and creative products.

Despite popular stereotypes of children just sitting and staring at the screen, several studies suggest that, cognitively, the child viewer is far from passive when watching television. This does not necessarily imply that the amount of mental effort children invest in processing television programs is large. Gabriel Salomon has demonstrated that, for older elementary school children, television viewing requires less mental effort than does reading. However, it has never been investigated whether this leads to a general tendency to expend little mental effort, including a diminished tendency to invest mental effort in imaginative play or creative activities.

Of course, child viewers consume fantasies produced by others, but there is little reason to assume that this leads to reductions in fantasy play or creativity. Children who read stories, listen to radio stories, or watch plays also consume fantasies produced by others. But nobody has ever argued that print stories or theater hinder children's imaginative play or creativity. Therefore, there is little reason to assume that television's reductive effect on imaginative play and creativity is caused by a television-induced, passive, "let-you-entertain-me" attitude.

THE RAPID PACING HYPOTHESIS

The rapid pacing hypothesis attributes television's reductive effect on imaginative play creativity to the rapid pace of television programs. According to this hypothesis, the child viewer is confronted with images that must be instantaneously processed, because scenes are presented in rapid succession. Children are thus allowed little time to process the information at their own rates or to reflect upon program content. The hypothesis argues that rapidly paced television programs encourage cognitive overload, impulsive thinking, hyperactivity, and a nonreflective style of thinking. Because both imaginative play and creative tasks require children to fix their attention for a longer period, the quality or quantity of imaginative play and creative products could be impaired.

Of course, rapidly paced programs leave children less room for reflection on program content than do slowly paced programs. Until now, however, there are no indications that a rapid program pace per se leads to cognitive overload, impulsive thinking, and shortened attention spans. It is no surprise, therefore, that none of the existing studies has demonstrated that program pace affects children's imaginative play.

THE VISUALIZATION HYPOTHESIS

This hypothesis attributes the reductive effect of television on creativity to the medium's visual nature. It is argued that television, unlike radio and print, presents viewers with ready-made visual images and leaves them little room to form their own images. When engaged in creative thinking, children find it hard to dissociate themselves from the images supplied by television, and therefore they have difficulty generating novel ideas.

Seven so-called media-comparison experiments have been designed to test the visualization hypothesis. In these experiments, children were presented with either a story or a problem. The text of the story or problem was usually kept the same, whereas the presentation modality (i.e., audio versus video) was manipulated. For example, half the children received the story in audio format, whereas the other half received the same story in audiovisual format. After exposure to the stimulus material, children were asked to complete a story, to write a problem solution, or to create a drawing based on the stimulus materials. These creative products were usually scored on novel (i.e., stimulus-free) ideas.

The majority of the media-comparison experiments showed that verbally presented information evoked more novel ideas than did television information. According to the authors, the television presentations

led to fewer novel ideas than the radio and print presentations did because children in the video condition had difficulty dissociating themselves from television images during creative thinking.

CONCLUSION

The studies conducted so far suggest that watching a lot of television might hinder children's imaginative and creativity. However, the research has paid little attention to the content of television programs. There is some evidence that creative children's programs may actually stimulate imaginative play and creativity.

IMMIGRANTS, MEDIA USE BY

Children and young people with a background of migration are often described as "between two worlds." The role of the media in the process of cultural change that accompanies migration has not been extensively explored. However, migration movements in Europe in the late 20th century evoked interest among media scholars in studying the media's importance in the process of migration, both for maintaining bonds with the homeland and for integration into the new country. This research also provides a useful picture of how immigrants use various media in developing their sense of identity. A positive implication of being both "here and there" when it comes to media output and content is that migrant families are alert to and conscious of cultural differences that range from differences in morals and values to differences in formal features of programming, such as formats and genres. These experiences seem to create reflexive and conscious media recipients.

IDENTITY AND CULTURAL CHANGE

Identity is a central concept in the behavioral and social sciences. Authorities in these fields claim that the identity concept is important for many reasons. For example, the quest for identity can be seen as an aim of minority groups who want to assert their distinctiveness and gain recognition. The globalization of the economy and of information flow, along with intercultural encounters on a hitherto unprecedented scale, brings the question of identity to the fore. The concept of identity is closely tied to modernity and the individualization of social life, that is, to the project of self-realization. Issues of identity are of crucial importance for people who are in the process of cultural change. For example, moving from a so-called traditional society with its expectations and role distributions to a modern society in which individuality is advocated renders the question of identity formation paramount.

Daniel Dayan (1999) stresses the need to study media use within the private sphere to find out about how the media are involved in identity formation, both in the maintenance of cultural identity and in the cultural appropriation and the creation of new identities. Furthermore, globalization of the media and new media technology create new spaces for cultural meeting points, which fact further emphasizes the need to capture how people in a process of cultural change navigate in the global arena of electronic media. As Anthony Giddens points out, new media technology also has also led to an increasing separation between the concepts of *place* and *space* in late modern society. The former refers to the physical location of a person, whereas the latter is independent of a specific place or region. For example, the Internet makes it possible to communicate and to maintain and develop social relations with so-called absent others, thereby creating a social space. Other scholars, such as Joshua Meyrowitz and Manuel Castells, stress that factors such as global travel, communication technologies, and mass production of identical clothes and other

products are making the world more and more interconnected. But Meyrowitz also stresses that physical places have not vanished and still provide settings for many of our interactions. Thus, the Internet may not only promote cultural change but may also help preserve cultural structures or patterns.

Marie Gillespie has studied the role of television and cultural change among young people in the residential area of Southall, London, which has a high population of immigrants from Punjab in India. Her extensive ethnographic fieldwork, which includes interviews and observations in various social situations, revealed evidence of proliferation and polarization of identities, a strengthening of existing local identities, and the formation of new ones.

Social scientists have for some time studied how children and young people use the media in the process of growing up. Their interest in media such as movies, television serials, and soap operas is well documented, and such programs seem to be mediators in the process of identity formation. The situation is, to a great extent, the same for migrant children and young people but is also somewhat different and more complex because of factors such as turbulent lives as refugees or movement from one country to another. Even second-generation migrants may perceive the presence of cultural change through their parents' eyes—through their narratives and life experiences. There is reason to believe that the media, especially new media such as the Internet, play a new role in this process of cultural change.

These conclusions are based on findings from a recent study conducted by Ingegerd Rydin and Ulrika Sjöberg, which provides a broad and detailed picture of how the media are used among migrant children and youth. It is based on in-depth interviews with migrant families who live in Sweden and who come from many different parts of the world (Asia, the Middle East, Africa, and Europe).

TELEVISION

Television is the most often-used medium among migrant families, at least for those living in the West. Besides watching programs from global and national channels, many families also have access to satellite television that provides programs from the homeland. This pattern of television use shows its unique role as a central element in media use by migrant families. Television is not only a shared experience but also a topic of conversation among family members and friends.

Language and Roots: Television as Mediator

National television is of great importance in learning new languages, but at the same time satellite television is used for preserving the mother tongue. Language learning by television can take many forms; for example, children often have a better mastery of the majority language than their parents and may translate difficult words and concepts as parents and children watch the news together. Most important, however, is the use of satellite television to preserve the mother tongue and culture and to inform the children about the country of origin, thus passing the parents' cultural heritage to a new generation. The parents tend to stress the positive emotional value of access to homeland television. It becomes a means of strengthening the bonds with the homeland.

National, Homeland, and Global Television

Although migrant children living in Europe sometimes watch programs in the mother tongue, they have a viewing repertoire of global programs, including American and British programs as well as entertainment programs from other European countries. Parents, on the other hand, often have a preference for programs in the mother tongue. If they come from unstable areas, they may watch satellite television to stay up-to-date with the latest news on war and violent incidents. This difference may depend in part on language proficiency. Children may be more comfortable in the majority culture's language as well as a foreign language; for example, in many places, such as Germany and the Scandinavian countries, children may know English as well as the majority culture language and the mother language spoken by their parents, whereas their parents are likely to be more comfortable in the mother language.

INTERNET AND COMPUTER USE

In Western Europe, access to the Internet has increased rapidly since the end of the 20th century. The Internet plays a special role in the process of cultural change. For example, in their 2002 study of Trinidadian families who live abroad, Miller and Slater refer to an "Internet family" rather than a "diaspora family" because the Internet plays such a crucial role in maintaining cultural roots. They also stress that all Internet use (and media use in general) must be

contextualized for each specific family. This interplay between real life and virtual life has been widely discussed among scholars with an interest in cyberspace. During recent years, attention has also been given to how online life and offline lives are connected. Thus, these two types of experience are perceived not as opposites but as parts of a mutual interplay. In 2003, Bakardjieva studied online forums and found not only that the Internet creates a kind of virtual togetherness but also that actions and interactions on the Internet are closely intertwined with participants' offline projects and pursuits. In her 2003 study on use of information and communication technology (ICT) among Turkish, Moroccan, and Surinamese youth in the Netherlands, d'Haenens also stresses the importance of contextualization of media use, arguing that research within this area should consider variables such as degree of integration, as shown in language knowledge and social life at large.

It is also important to keep in mind that the opportunities offered by media such as the Internet have different meanings and implications for various social groups within Western societies. First, migrant families are often among those people in the West whose computer access is limited by socioeconomic circumstances. Second, Internet access it is not equally distributed in the European community; families in northern Europe, including migrant families, are "wired" to a greater extent than those in southern Europe.

Keeping in Touch: The Internet as Mediator

The Rydin and Sjöberg study shows that, among migrant families living in more developed countries, the Internet seems to be a way to keep informed about current political and social events, and in many cases it has replaced newspapers that formerly were read at the library. Other common uses are listening to radio or downloading music from the home country. MSN Messenger and email have been important complements to traditional means of telephone communication for adults and children alike. It is not a matter of new technologies replacing old ones but rather a combination of these. This different function and purpose of use is also stressed in a 2002 study by Daniel Miller and Don Slater, which found that less expensive Internet communication has replaced the telephone for casual information exchange. The telephone is reserved for important news exchange, on special occasions and lifetime events such as births, marriages, and deaths, or for children's staying in touch with cousins and friends in the home country. The telephone is also used for communication with those who have no access to the Internet, which is common in less-developed countries.

When they have a choice, children seem to prefer the Internet as a form of communication. Frequent communication is common among children who have recently arrived in the new country and may suffer from homesickness. In her 2003 study of 12-to-19-year-old Turkish, Moroccan, and Surinamese youth in the Netherlands, d'Haenens found that the extent to which children identified with their homeland was strongly correlated with their need to search for information about the country of origin and to maintain contact with other youngsters with the same ethnic background and culture. Internet communication varies among immigrants depending on the access their families and friends have to the Internet, which in turn depends on what country they are from and whether their relatives live in a city or in the country.

A main difference between adults and young people is that the Internet is a part of local youth culture and thus provides a close link to the young person's life in the new country. The Internet is used to chat with peers from school, to play online games (among the boys), to listen to music (usually mainstream pop music, R&B, or hip hop), to read about specific interests such as bicycling or cars (mentioned by boys), and to search for information related to schoolwork. The Rydin and Sjöberg study found that gender also plays a role: Boys play games on the Internet more often than girls do, and boys regularly visit sites about certain topics such as sports and cars. This medium has in fact replaced the telephone for continuing school conversations after school. Thus, youth share an online culture, an extension of playground gossip and interaction.

OTHER MEDIA

European studies also indicate that watching films on DVD or VHS is popular among migrant children. The choices reflect both cultural origins and the need to build new peer relations. The repertoire seems to be a mixture of Hollywood productions and movies from the home country. Some children also watch home videos of family events, such as weddings and other celebrations related to their cultural origins. These videos are also exchanged among communities of same origin. The same pattern is seen when it comes to music, although music listening is a more private

activity than watching videos. Children often have their own CD or cassette players, and they seem to have the same music favorites as young people in general, including rap, hip hop, R&B, and mainstream Western pop music. In addition, however, migrant children have access to the music of their cultural origins. There are, however, some variations in music practices between ethnic groups. For example, karaoke is popular within Vietnamese diasporic communities, whereas ethnic folk music is important to young people from the Middle East and the former Yugoslavia.

Little research has been done on the use of print media by migrant children. Swedish data from the Rydin and Sjöberg study, however, indicate that reading Swedish literature and magazines is seen as a means to learn Swedish. Because these children often come from less-privileged families, they do not always have access to books at home but borrow them from the local library.

THE NEW COUNTRY VERSUS THE HOMELAND

The concepts of *here* and *there* are crucial in immigrant families' lives. This dichotomy constitutes a main feature of the parents' perception of themselves in the new country. But European studies of migrant children from many different parts of the world indicate that this theme is less pronounced among children, compared to adults. On the whole, young people seem to be more integrated, and generally act as children and young people with a focus on *here*. Migrant children adopt the same global media culture as the majority culture's youngsters, not necessarily related to cultural bonds or ethnicity. For example, boys play mainstream computer games not only with peers in their local community but also with others in distant parts of the world.

The dual presence of homeland versus host country in the minds of migrants is a concrete indication of the awareness of cultural change. In this process of cultural change, which ideally leads to participation in society, learning about the new country is necessary. One important part of this process is knowledge of the language of the majority culture. On the other hand, watching satellite television can provide an important link to the homeland and can be a means to maintain or establish contact with the culture of origin to future generations.

INDIA, MEDIA USE IN

As the second most populous country in the world, India provides an immense market for media of all kinds. Between the traditional news media—newspapers and radio—and the more modern outlets such as television and the Internet, hundreds of millions of Indians are reached, informed, and entertained on a daily basis.

Moreover, thanks to the emergence of an economically prosperous Indian middle class (believed to number over 100 million people), the adjacent industry of advertising is growing, at the beginning of the 21st century, by leaps and bounds, further stimulating the development of diverse, financially stable Indian media.

With 55,000 newspapers published in two dozen languages, the most prolific movie industry in the world, and a rate of investment in TV advertising roughly twice that of the global average, India has rapidly become not only a huge media market but also one of the world's preeminent media producers and operators. An increasingly large, young demographic group has developed a ravenous appetite for entertainment-oriented media content, prompting increased attention from both media makers and media watchers. The increased penetration of the Indian market by various media is predictably attracting more and more scholarly investigation, as well as more discussion in the public sphere, of the potential benefits and disadvantages presented by such phenomena as television, the Internet, and cinema to the Indian public in general and to children in particular.

Bombay residents walk past billboards featuring a 1996 box office hit, *Raja Hindustani.* The movie follows a melodramatic plot familiar to all consumers of Bollywood productions: Two young individuals (in this movie, played by prominent actors Aamir Khan and Karisma Kapoor) fall in love with each other and decide to get married against parental wishes. Partly due to the formidable success of such time-honored plot recipes, the Indian film industry is able to claim the largest output of movies in the world.

THE HISTORY OF INDIAN MEDIA

Like most aspects of modern Indian life, the beginning of the national media was heavily influenced by the British Empire's political and economic control over South Asia. As early as the 16th century, European Christian missionaries brought printing presses to India. Until 1780, however, no newspapers were published in a region of the world that was increasingly coming under the economic (and hence political) control of the British East India Company. The first Indian publication was a weekly journal, edited by an Englishman, that contained accounts of the British Empire's faraway battles, news about European affairs, and political attacks against selected English notables in the Indian colony.

In 1819, the city of Calcutta saw the emergence of India's first daily newspaper, and two years later the man who would later be called "the father of the Indian press," Rammohun Roy, launched three journals written in English, Persian, and Bengali, advocating for social reform in India, which they said was urgently needed. It was the beginning of a national press that saw itself as responsible for the education and emancipation of the Indian people. These concerns were shared by the media, which intensely reported on and debated the 1947 proclamation of independence from the British Empire and the subsequent partition of the region between India and Pakistan.

THE PRINT MEDIA

India is currently still designated by economists and political scientists as a "developing country." Despite its status as the world's 11th largest economy,

a significant percentage of its billion-strong population lives in dire poverty. As a result, as of 2003 the literacy rate in India was as low as 59%. The country's socioeconomic environment naturally also shapes the profile of its regional and national media in terms of the viability of the news industry and the public's access to information. Praised by outside observers for the relative quality of their content as well as their sheer number, the Indian print media can be faulted for their lack of penetration of some of the country's classes and social groups. Predictably, city dwellers enjoy higher accessibility to media than do the inhabitants of rural regions.

Upwards of 2,000 daily newspapers vie for the loyalties of the one quarter of India's population who are regular consumers of print media. Since 1966, Indian newspapers and news agencies have been supervised by an autonomous, quasi-judicial body called the Press Council of India, which has the power to censor publications as it sees fit. Regarded as one of Asia's most independent media systems, the Indian press has not entirely escaped the taint of a corruption that in 2004 earned the country a middle spot in Transparency International's ranking of most corrupted states.

CHILDREN AND TELEVISION IN INDIA

A rising standard of living throughout India's cities, coupled with a genuine country-wide explosion of broadcast media, has led to an increased familiarity on the part of Indians with the uses and misuses of television. More and more children below the age of 18, who make up more than 40% of India's total population, live in a world shaped in many respects by this powerful medium. A 2000 UNESCO report estimates that, as far as children are concerned, the distribution of Indian television viewership matches the distribution of the country's total population. Children constitute 40% of all viewers—a finding tentatively explained by media effects scholars in terms of an observed tendency in India toward family viewing (as opposed to individual viewing). According to a 2002 study undertaken by Suman Verma and Reed Larson, 73% of the Indian adolescents who watch TV do so as a family activity. This situation may have both positive and negative effects on juvenile attitudes and behavior. On one hand, watching television in the family affords parents an opportunity to enact effective programming control and mediation. Indeed, a 2002 study based on a sample of English-speaking (and thus reasonably affluent) families indicated that a majority of Indian parents have instituted rules for their children's TV viewing. On the other hand, the presence of parents in front of the TV set might lend violent and often sexually explicit images an aura of parental sanction.

PROGRAMMING AND CONSUMPTION

One of the major consequences of India's drive toward economic liberalization at the beginning of the 1990s was the almost instant mushrooming of satellite television channels. The heyday of the state-owned television network Doodarshan (which had enjoyed a monopoly since 1959) came to an end as global media giants unleashed an aggressive marketing campaign aimed at the burgeoning urban middle class. As a result, Doodarshan's most popular Indian epics, *Ramayana* and *Mahabharatha*, were forced to compete with Western feature films and serials. The new kind of programming appealed to many of India's middle-class adolescents, particularly to those fluent in English (a characteristic of elite education in India). As far as Indian-produced television is concerned, however, no more than 5% of all programming is targeted to children, and virtually no programming is tailored for children younger than 5 years. The existing children's television is of low quality due to the low priority that TV producers and managers assign to preadolescent and adolescent audiences. As a result, children view much the same content as their parents: Indian and Western soap operas and feature films. Studies show that the typical adolescent viewer in India spends 2 to 3 hours in front of the TV daily, primarily in the evenings. Teenagers interviewed by sociologists and communication scholars have reported high levels of interest in entertainment-oriented shows, to the detriment of informational programming.

MUSIC AND THE "YOUTH CULTURE"

With the advent of satellite technology, the music television industry, driven by Viacom's MTV India and News Corporation's Channel [V], is quickly moving to capture the imaginations—and disposable income—of India's youth. Indeed, the two music channels are credited by many observers to have almost single-handedly created a veritable "youth culture" in India, characterized by an excessive valorization of consumption and self-image. In large measure due to MTV's and

Channel [V]'s popularity with adolescents and young adults, India's music market has become the second largest in the world in unit sales. Despite its ownership by Western corporations, the two music channels have built their preeminence on nationalist Indian music, often engaging with each other in a genuine "arms race" of "Indianization." Bollywood-inspired film songs and music videos dominate the channel's programming, followed at a considerable distance by the relatively new genre of Indian pop and the even newer, diaspora-inspired music, such as the London-based group Banghramuffin. Indian music stars manufactured and marketed by the two channels consistently edge out Western singers and bands in popularity surveys among the young.

BOLLYWOOD'S SLOW TRANSFORMATION

By far India's most popular mass medium (both within the country and outside of it) is the cinema. The biggest feature film producer in the world, the Indian movie industry releases more than 800 productions every year, more than double Hollywood's output. Bollywood—as Indian cinema is known throughout the world due to the concentration of movie-making infrastructure in the western city of Bombay—benefits from an immense consumer base, with more than 10 million Indians buying a movie ticket every day.

Unlike Hollywood productions, Indian movies do not generally cater to niche audiences. Few productions, therefore, specifically target the adolescent or young adult populations. Instead, the movies are predominantly an family affair, with members of three different generations often going to the movies together. Moreover, Indian audiences tend to engage with the screen characters more than their Western counterparts in terms of frequent loud commentary on ongoing interesting scenes. By and large, Bollywood movies still follow a common pattern: They alternate dialogue and action shots with song-and-dance routines, incorporate both dramatic and comedic elements, and include a romantic narrative (preferably centered on the traditional love triangle)—all in the span of 3 1/2 hours per film, on average.

In recent years, however, seeking increased revenues, many Bollywood movies have taken a cue from Hollywood blockbusters and have largely forgone the decorum that characterized the industry for decades. Whereas "traditional" Bollywood musicals avoided depicting even so much as a kiss between two romantically involved characters, recent productions have included explicit sexual scenes, profanity, and high levels of violence. Aware of the connections between the movie theatre space and the adolescents' penchant for group entertainment, an increasing number of Indian social scientists, community leaders, and NGO media watchers are taking a stand against the negative effects the widely popular Bollywood movies are thought to have on the psychological stability of India's youth.

THE DIGITAL DIVIDE

Driven by a flourishing economy and by an abundance of software engineers, the Internet has established a strong foothold in India, with over 39 million users as of 2005 (a sixfold increase since 2000). In recent years, the Indian Ministry of Communications and Information Technology has launched a campaign aimed at making it easier for consumers to purchase PCs (increasingly priced at less than $250 per unit), reducing license fees for Internet operators (resulting in broadband connections as cheap as $4 a month), and developing various language fonts for websites and email. Despite these efforts, the Internet is available only to a minuscule 3.6% of the entire population, with rural areas in most of the Indian states completely devoid of digital coverage. Indian Internet users account for 11.8% of all users in Asia, compared to 31% for China and 23% for Japan. Most of India's Internet traffic is domestic, but it is routed through outside exchanges in the United States or elsewhere. The 18-to-35 age group is the predominant consumer of Internet-based services, although the 45-to-65 category is increasingly familiarizing itself with the digital world. More than 98% of Indians online use email daily, with job search accounting for 51% of all Internet use and e-banking trailing at 32%.

INDIGENOUS MEDIA

Indigenous cultures are very diverse and have different ways of viewing the world; each has its own history, language, culture, and manners of expression. This traditional culture is passed from generation to generation, and although indigenous youth are part of the mainstream culture, they are also benefactors of the traditional cultures passed down between the generations. Many of these indigenous youth groups have recently flooded into the electronic media and have used every avenue of media expression from television, radio, and movies. Worldwide, there is a vast network of indigenous youth involvement in the media. The Internet and other media allow indigenous youth to be a part of global culture while also helping them to express their unique cultures.

Indigenous people have typically inhabited a country for thousands of years, but in contemporary society most of them have become minorities in their own homeland due to colonization and immigration. While the majority of people living in the United States, Australia, New Zealand, Hawaii, and other places are immigrants, the original inhabitants of the lands are the indigenous peoples, the traditional owners of the land. Some of these original inhabitants prefer terms other than *indigenous*. For example, in Australia, the people who have lived there for thousands of years are termed *Aboriginal* and *Torres Strait Islanders*. In Canada, the people who have lived there thousands of years are called *First Nations, Metis,* and *Inuit*. In Hawaii, the people who have lived there thousands of years are termed *Native Hawaiian*. In New Zealand, the original islanders who are called *Maori* prefer the term *Tangata Whenua*, or "people of the land."

INDIGENOUS YOUTH AND MEDIA

Indigenous media constitute a diverse and rapidly growing field. Such media appear so widely on the Internet and in videos, movies, television shows, and print (newspapers as well as books) that it would be difficult to catalog all media expressions. Additionally, cultural differences between indigenous groups make it difficult to ascertain and compare indigenous media. Some indigenous groups, for example, have strict codes of behavior about showing images; sometimes these codes of behavior are respected by the youthful generations, and sometimes they are not. Other groups have protocols for showing pictures of the dead, and still other groups do not allow graven images to be taken. Most indigenous groups, however, are very visual, and visual media have become a culturally congruent form of communication. For this reason, many indigenous youth groups have developed a wide range of media products to communicate their unique point of view and to have a voice in contemporary society. Ginsburg (1994b) calls this *cultural activism* and suggests that, through cultural activism, indigenous youth and adults bring both their politics and their culture to their media in an effort to be heard. Ginsburg (1994a) suggests that indigenous and minority people can use video, especially, as a means for communication both within and between communities and that video can aid the self-determination of an indigenous community by resisting outside cultural domination. Indigenous youth have taken this self-determination as a call to arms for self-expression. Australian aboriginal Torres Strait Islander youth have been leaders in this regard, as have First Nations and aboriginal youth groups in Canada.

TELEVISION

From the indigenous point of view, television may do more to promote negative stereotypes than it does to promote positive, healthy stereotypes of indigenous peoples. For example, in many Western television shows, as in Western movies, indigenous peoples are portrayed as savages and hostile enemies. In history, most indigenous peoples were actually defending

themselves against the hostile and aggressive attacks of colonists trying to overtake their homes and countries. Rarely does television show the impact of displaced tribes, stolen lands, broken treaties, or massacres. Hartley (2004) discusses the clash of indigenous culture with Australian television and suggests that indigenous cultural identities should be given more airtime on television to improve the way nations can eliminate the impact of such powerful negative stereotypes. For this reason, many indigenous groups are establishing their own television services. The Inuits in Alaska, for example, lobbied for a Canadian license to create the Inuit Broadcast Corporation (IBC) in the early 1970s. Two important stations are ABC's Message Stick and Imparja Television, both of which have websites and special programs for indigenous youth.

Young children's perceptions often first develop out of media portrayals. Unfortunately, Native American children first see negative or outrageously unrealistic images of themselves on television and through other media outlets. Merskin (2001) found that these images are a result of assumptions about Native Americans and contribute to negative stereotyping and racism. Merskin (1998) found that film presented more positive images of Native Americans than did television. Because children have television in their homes on a daily basis, this is of particular concern. Studies of the role of television in the development and maintenance of stereotypes are particularly troubling. Graves (1999), for example, showed that television reinforces and maintains stereotypes in children that potentially contribute to prejudice and discrimination, a finding confirmed by others (Rutland, Cameron, Milne, & McGeorge, 2005).

RADIO

Many radio stations are devoted to indigenous music, and most of these are broadcast over the Internet. KNBA 90.3FM, for example, is an eclectic mix of indigenous radio and talk that broadcasts international music and talk from Alaskan Natives, Native Hawaiians, and international music from around the world. Internet radio is also a strong communicator of the indigenous viewpoint. Two popular indigenous radio stations are Internet Radio @ Buffalo Trails and American Indian Radio on Satellite. Other radio stations, including ABC Radio's Awaye! and Speaking Out, also represent the indigenous point of view.

The Youth Internet Radio Network was a research project by Hartley and colleagues that investigated streaming website with content developed for youth and by youth. Youth participated in designing the Internet site and were trained to produce the creative content for the site. Through this network and website, they were able to discuss important issues and had a platform for local information. Youth across Queensland, Australia, were contacted via this Internet radio service, which successfully used the media to establish a culturally responsive mode of communication for youth.

VIDEO

Indigenous people have exploded into the film industry over the past two decades. Prior to that time, most films were made about indigenous peoples, not by them. Today, however, many films are made with members of indigenous tribes or ethnocultural groups serving not only as consultants but as directors, producers, and actors. Although he points out that surveys do not exist regarding just how many or what kind of work is produced by indigenous peoples, Leuthold (1998) comprehensively examines films produced by American Indians such as George Burdeau (Blackfoot) and Victor Masayevsa (Hopi). Nichols (2006) studied the use of video as a communication tool for an indigenous community in Brazil, the Kayapo tribe. She suggests that the negative side of video in indigenous communities has not been well studied. Video can bring Western culture into the indigenous community, with negative effects that result from the promotion of detrimental aspects of Western culture such as consumerism and substance abuse.

MUSIC AND ART

In indigenous cultures, cultural vitality has always expressed itself through art, especially music. Music, therefore, becomes a type of cultural expression, an important medium of communication, and a significant medium in and of itself. There are many examples of the influence of indigenous music on contemporary music, and many more examples of indigenous music as a natural reflection of the cultural traditions of specific ethnocultural groups. Native Hawaiian (Kekuhi Kanahele) music is legendary, from the deep chanting of the early Native Hawaiians to the soft, mellifluous flow of contemporary Native Hawaiian music, to the synchronicity of the Caribbean

and Hawaiian music known as *jawaiian*. This form of music is very popular with Native Hawaiian youth, who have made popular icons of many Native Hawaiin musicians. Popular Native Hawaiians such as Brother Iz (Israel Kamakawiwo'ole) have made an impression on contemporary Western music.

Indigenous musical instruments are typically used in indigenous music, such as Native American flutes, Native Hawaiian gourds, and Filipino wind and percussion instruments. Native Hawaiian youth have created a resurgence in the popularity of the ukulele; in Hawaii, as well as other areas of the country, the small stringed instrument has made a comeback in elementary and secondary schools. The Grammy Awards now have a Native Hawaiian and a Native American music category. Information and musical broadcasts of indigenous youth music can be easily found on the Internet, including music from South America, Australia, New Zealand, the Philippines, and Hawaii. The field of ethnomusicology, which is devoted to studying indigenous music, is concerned with researching and documenting indigenous music from around the world and promoting an understanding of it. Internet sites such as those listed in Table 1 a focus on the music of indigenous cultures as well as broadcasting interviews and indigenous news reports

Indigenous youth have used the Internet as a forum for artful expression. The Indigenous Media Arts Group sponsored a training program in 2004 for indigenous youth to use the media as a tool for self-expression. Students in the program learned about media literacy, media arts history, scriptwriting, digital video production, print media, writing for radio and DVD, and web design in a 5-month media training program. An exhibition of their resultant media productions was displayed on the website.

THE INTERNET

January 2004 concluded the International Decade of the World's Indigenous People, which was launched by a proclamation of the General Assembly of the United Nations. During that decade, there was an explosion of Internet resources for indigenous peoples. Multinational, national, and local community websites were developed to serve the needs of indigenous peoples around the world, and the Association of College and Research Libraries developed a catalog of quality websites for this purpose.

The Internet has held much promise for indigenous youth. The Index of Native American Media Resources on the Internet provides a comprehensive listing of media resources on the Internet for youth and adults, including websites for newspapers, comic books, music, journals and magazines, e-zines, documentary photography exhibits, broadcasting, and other types of information. Aboriginal Connections is another excellent site for indigenous youth.

The Internet has been especially helpful in producing content for indigenous youth that would ordinarily be restricted to small, local communities. Through the Internet, such content can reach rural and metropolitan areas across the globe. The Internet magazine *Redwire* is a good example of this. It has content developed by youth and covers a variety of areas including health, wellness, news, protection of resources, and art, among many other topics. Another good example is the Aboriginal Youth Network, an online resource

INDIVIDUAL DIFFERENCES, MEDIA PREFERENCES AND

Individual differences have long been used as a tool for understanding the content preferences of media audiences. Although earlier analyses of individual differences that focused on demographic and lifestyle characteristics were linked to audience media preference, more recent research has begun to shift the focus to psychologically based personality differences. Growing evidence suggests substantial congruity between the personality characteristics evinced by children and adolescents and their preferences for and use of different types of media content.

Traditionally, individual differences based on demographic characteristics such as age, gender, and race were used to build profiles of the broadcast, cable, and print media consumer. Indeed, audience data demarcated on the basis of demographic considerations remains the contemporary standard for understanding media content preferences.

Individual differences based on lifestyle and psychological characteristics—called *psychographics*—have been less strongly embraced by media professionals. Psychographics typically involve "fuzzier" concepts, such as attitudes, self-concept, and interests. Typically, psychographic information is combined with demographic data to provide a more refined image of audience media preferences.

Recent research has expanded the basic notion of psychographics to explore media preferences in terms of personality differences. In this endeavor, the broad array of habits and traits that characterize human nature are organized according to three distinct personality dimensions: extraversion, neuroticism, and psychoticism. *Extraversion* is a quality of individuals

who exhibit high levels of sociability and positive self-esteem. The term *neuroticism* characterizes individuals who exhibit high levels of emotionality and shyness and negative self-esteem. *Psychoticism* refers to individuals who display the characteristics of egocentricism, impulsivity, and social deviance.

Within this framework, a program of research initiated by James Weaver suggests that personality characteristics exhibited by mass media consumers can influence both their perceptions of the media and their preferences for media content. Individuals of the socially outgoing, extraverted personality type, for example, strongly reject the notion of using television as a functional alternative to interpersonal companionship. At the same time, however, individuals displaying neuroticism strongly endorse the use of television as a replacement for social companionship, to pass the time, and for both relaxation and stimulation. Further, these individuals view the television remote control device as a tool that enables them to avoid commercials and emotionally disturbing program content. Interestingly, viewers of the psychotic personality type see the television remote control as a tool with which to annoy and tease coviewers.

Taken together, these findings illustrate considerable correspondence between audience members' personality characteristics and their perceptions of television. This same pattern of congruency is also evident for the television viewing habits of children. One study of a very large sample of 9-to-15-year-olds in the United States found that children who evinced personality characteristics consistent with the neurotic personality type (e.g., anxiety, depression, dissociation, anger) were exceptionally heavy viewers (more than 6 hours a day). A similar pattern was revealed in a study of 9-to-10-year-olds in Italy: Children reporting the neuroticism trait of emotional instability watched television the most (3 hours per day or more). Additionally, children reporting traits consistent with psychoticism (e.g., low levels of agreeableness and conscientiousness) were moderate television viewers, whereas those of the extraverted personality type used television the least.

Research evidence also highlights extensive concurrence between audience members' personality characteristics and their media content preferences. Individuals of the neurotic personality type, for example, express a strong preference for informative and news television content and "downbeat" music and tend to avoid lighthearted comedy and action-adventure fare. Content facilitating sociability, such as "club" or "party" music, and content promoting social activities, such as party-themed movies, are strongly preferred by individuals exhibiting extraversion. Individuals presenting the psychotic personality type showed a strong preference for socially deviant content such as graphically violent horror movies and "hard" or "rebellious" rock music videos. Research involving children, although limited, illustrates similar media content preference patterns. One study involving 12-to-14-year-olds in Spain, for instance, found that frequent viewing of popular films involving violence (e.g., *Lethal Weapon*, *Robocop*, *Rocky*) was positively associated with the extraverted personality type in girls and the psychotic personality type in boys. Although the generality of the film viewing measure makes it difficult to precisely discern the children's viewing motives, it appears that the social activity of moviegoing underlay the interest of the females, whereas males sought the vicarious experience of watching violence. Other studies show that one personality trait that defines the psychotic personality type (namely, the sensation-seeking dimension of disinhibition) is positively related to adolescents' exposure to violent television, film, video game, and website content, whereas a sensation-seeking dimension consistent with the neuroticism personality type (namely, experience seeking) is negatively linked to adolescents' violent television viewing.

Are these patterns of relationships between personality and media content preferences reliably evident across cultures? We can answer this interesting question with a qualified "Yes." Although it has long been recognized that personality characteristics are consistent across cultures, recent research highlights the fact that media content considered socially deviant is uniquely defined within each culture. This fact was demonstrated in a study comparing the movie preferences of American and German college students. High-psychoticism individuals living in the United States reported a preference for movies with sexual themes, whereas those in Germany preferred violent movies. Consideration of how sexual and violent media content is perceived within each culture helped illuminate the observed difference. In Germany, depictions of violence are prohibited, whereas media depictions of sexuality are readily available and consequently may have been considered mundane and passé by German respondents. An opposite pattern is evident in the United States: Media content involving explicit sexual themes is considered socially deviant,

whereas depictions of violence are common. Thus, the findings reveal that individuals high in psychoticism prefer media content that is deemed socially deviant within their cultures.

INFANTS AND TODDLERS, DEVELOPMENTAL NEEDS OF

Infants and toddlers under the age of 2 live in a media-saturated environment. They are fed in front of television screens, sit on adults' laps in front of computers, play with music in the background, and may even have tape recorders or computer keyboards designed for babies. However, the limited research conducted in this area has focused almost entirely on television. Some studies have addressed the impact of television on attention, language development, and learning more generally. Variables such as the kind of content viewed and the nature and extent of parental mediation appear important to an understanding of television viewing's effects on infants and toddlers.

SENSORIMOTOR EXPERIENCE

According to developmental theories, the baby-toddler passes through the sensorimotor stage during the first 2 years, in which mental schemas are shaped by the infant's senses and actions. For example, a baby may learn about the unique world of television by such actions as touching the screen when a favorite puppet appears, clapping hands to the music, or playing with the power button. These sensorimotor experiences are gradually integrated into the child's developing understanding of television and social reality. Thus, the child comes to understand that touching a puppet on a television screen feels very different from touching a favorite stuffed animal in the crib, and that, although television can be turned on and off at will, an absent caregiver does not return at the press of a button.

ATTENTION AND COMPREHENSION

Attention to television develops from birth. In describing attention, researchers distinguish between *foreground television*, or television content to which young viewers attend closely, and *background television*, which may operate as background noise in a room where the young child is engaged in other activities. Newborns of a few weeks have been observed to react to sounds coming from the television set by stopping their feeding and turning their heads toward it. During the first few months of their lives, babies

depend mostly on audio cues that direct their attention to background television for few seconds at a time. As they mature, young viewers engage in more foreground viewing, especially viewing of television programs and videotapes designed especially for younger audiences and clearly more comprehensible to them. Such programs, as well as commercials, can hold babies' attention for much longer stretches of time. Entrepreneurs have recognized this fact; consequently, there has been a recent growth in the number of programs and videotapes designed for viewing by this very, very young audience.

Particularly attractive television features are peppy music, sound effects, animation, lively pacing that is not overwhelming, laughter, and pleasing colors and shapes. Babies seem to react to content that makes sense to them: short verbal outputs, smiling faces, lovable animals, and female and children's voices. Studies of home observations of babies, as well as reports from caregivers, suggest that, from the age of a few months, babies will often stop their activities, move to the music, clap their hands, make happy gurgling sounds, and toddle toward the television set to point at objects and characters on the screen. Preference for familiar contents viewed with pleasure over and over again intensifies during the second year of life. Observations have documented high levels of attention and active viewing on the part of toddlers, which included singing and dancing along, pointing to the screen, imitating behaviors, speaking back to the television, and generally reacting enthusiastically and with great joy.

Babies and toddlers' attention to television is greatly influenced by the behaviors of people around them. For example, placing a baby on one's lap or cuddling the baby in front of the television will significantly lengthen his or her attention period. Food, too, seems to ensure longer periods of satisfied concentration—babies offered a bottle or a snack while viewing continued to be relaxed, attentive viewers.

By the end of their second year, toddlers' viewing sessions gradually lengthen, with signs of growing interest in the animation genre. Although accurate measurement of attention to television in babies and toddlers is a complicated matter, researchers claim that the amount of time spent with television grows dramatically, particularly during the second year of life. The amount of viewing varies greatly, however; some babies do not watch any television, whereas others may view 1 to 2 hours daily on a regular basis. At around 2½ years, on average, many youngsters are able and willing to stay tuned for a full half hour or even more to a program they find of interest. This age coincides with the transition into the language-oriented, preoperational stage of cognitive development, with all the physiological and social changes typical of this age group. Thus, contrary to the claim that toddlers (as well as children from older age groups) are "hypnotized" by the screen, toddlers clearly demonstrate very frequent changes in orientation from the screen to the surrounding environment and back.

VIEWING AND LANGUAGE DEVELOPMENT

A common criticism of excessive television viewing at a very young age is that it hinders the development of language, a central cognitive task for babies and toddlers. There is some research evidence to support these claims, as the quality and quantity of parent-child interactions have been found to be significantly reduced in the presence of background television. However, the distinction between background and foreground television is useful here, as other studies point to the possibility that parental mediation and viewing of age-appropriate programs may stimulate language learning. Studies have found that infants and toddlers benefit most from viewing programs that apply specific linguistic strategies appropriate for this age group, as when actors on television speak directly to child viewers, encourage their participation, engage in object naming, provide opportunities for children to respond, and the like. Watching programs that use attractive storytelling formats has also been found to be associated with positive language development.

Indeed, the few observational studies and parental viewing logs that have followed the language development of babies and toddlers in their home environments suggest that some parents use television as a "talking book" with their young ones. They practice linguistic skills during television viewing, particularly with programs aimed at the very young. For example, both children and parents may designate objects and characters on the screen by name (e.g., "Here is a balloon! This is a butterfly!"); may ask questions (e.g., "Where did they go? What is she doing?"); may repeat messages, including commercials and slogans; and may describe what they see (e.g., "He is sad" or "They are playing with the dog").

Overall, these studies suggest the importance of paying attention to program types and content in

considering the effects on language development, because the viewing of different programs may have different types of influence on language development (as well as other aspects of development).

TELEVISION VIEWING, COGNITIVE DEVELOPMENT, AND LEARNING

A few studies have focused on the possible relation between the significant presence of background television noise in the first few years of life and less reading and poorer cognitive development in general at an older age. In addition, a few experimental studies that examined learning from videos presented to viewers under 2 years of age were quite consistent in indicating that very little learning occurs under such conditions, and that it is dramatically less than that found for equivalent live displays of behavior. Such was the case for experimenting with learning imitation from televised behavior, for searching for hidden objects, and for learning positive versus fearful emotional reactions. Taken together, these studies suggest that learning from television by children under the age of 2 is limited and that exposure to television at this age is associated with negative outcomes. This may be explained in part by the nature of development in the sensorimotor stage and the nature of television as a symbolic, representational medium. At this age, young viewers still lack symbolic awareness and have immature cognitive skills (e.g., perceptual, linguistic, and attentive skills). The findings of these studies raise important substantive as well as methodological questions about studying very young viewers, but they are too few and far between to suggest any firm conclusions.

EARLY COMPUTER USE

Very little is known about the growing phenomenon of early computer use by infants and toddlers. One such study in the United States found a socioeconomic and racial divide in early childhood access to and use of computers and the Internet. Early computer use seems to develop in the second year of life, generally while the child is seated on a parent's lap, and through use of special keyboards designed specifically for babies. For both boys and girls raised in homes with computers, computer-related skills develop rapidly during the third year of life, but to date there is no research-based knowledge about the nature of this process.

PARENTAL MEDIATION

Parental mediation is a central variable in all aspects of young children's media-related behaviors—in controlling the amount and type of exposure to media, interacting with children about such contents, reinforcing certain behaviors, and the like. More specifically, children who are raised in homes with viewing-time rules (i.e., rules about the amount of viewing time) tend to spend less time in front of the screen. However, this was not the case for children raised in homes that applied program rules (i.e., rules about the type of programs viewed), where parents were more likely to hold positive attitudes toward television and to mediate viewing itself. Finally, viewing rules develop as children grow older and were found to be associated with higher socioeconomic status.

THE AMERICAN ACADEMY OF PEDIATRICS' RECOMMENDATION

Since its inception, the television market for the very young has grown significantly, raising new questions about television and very early childhood. This trend was inspired by a highly controversial recommendation by the American Academy of Pediatrics in 1999 that discouraged all forms of television viewing before the age of 2. Based upon very limited research evidence, the assumptions behind this recommendation were that television viewing hinders physical, emotional, and cognitive development because young viewers are for the most part passive and are bombarded with too much audiovisual stimulation, and because viewing television takes time away from social interactions with adults and children alike. However, the limited number of existing studies to date cumulatively suggest that the impact of television on development is determined not by viewing television in and of itself but by the type of program content, the amount of viewing, the viewing circumstances, the alternatives available to the youngster, and the form of parental mediation that occurs in conjunction with viewing.

INFANTS AND TODDLERS, MEDIA EXPOSURE OF

Since the 1990s, there has been a large increase in age-appropriate programming for infants and young children as well as a recent increase in television exposure during infancy. The effects of background television exposure on play, and the fact that infants learn less from television than from live demonstrations, limit what infants can gain from television exposure. On the other hand, the fact that repeated exposure to televised segments enhances imitative and language learning, as well as evidence of the beneficial effects of television on older children, suggest that television has the potential to provide positive and cost-effective benefits during infancy and early development. At present, the long-term effects of early media exposure on social and cognitive development are largely unknown. Researchers are examining how specific kinds of exposure to commercial programming influence early development and what kinds of experiences help young children understand and decode the symbolic nature of screen media.

MEDIA EXPOSURE

American children are born into and develop in a world in which media pervade their daily experiences. A recent nationwide survey, conducted by the Kaiser Family Foundation, of 1,000 homes with children aged 0 to 6 years found that that 99% of homes contain a television set, 95% have a DVD player or a VCR, 50% have three or more televisions, 73% have a computer, and about a third of U.S. children have televisions in their bedrooms.

Media content for infants and young children is also changing and has been accompanied by an increase in children's television exposure. During the 1970s, children were first exposed to television on a regular basis at approximately 2.5 years. During the 1990s, television programs such as *Teletubbies* and videos and DVDs such as *Baby Einstein* started to be produced specifically for infants. This has shifted the age of regular exposure. The Kaiser study reported that many infants begin consistently viewing videos and DVDs at 6 to 9 months; 74% are exposed to television before age 2, and those exposed spend approximately 2 hours per day with screen media, predominantly television, videos, and DVDs. Computer experience and video game play are relatively rare prior to age 2 but increase in frequency during the early preschool years. By contrast, these children spend only about 40 minutes a day reading books or being read to. Furthermore, 72% of parents in the Kaiser study believed that early exposure to computers was "mostly helpful," and 58% believed that early exposure to educational television programming was "very important." Patterns of television use differ across ethnicity; African American and Latina/o children spend more time watching than Caucasian children.

Finally, availability influences levels of television exposure. When children have televisions in their own rooms, they are exposed to a greater amount of television. In a household where there is heavy television viewing, defined as having the television on most or all of the time, children have higher levels of television exposure; they begin watching at an earlier age, are more likely to watch television every day, and watch it for longer periods of time. Children in heavy television-viewing households are also significantly less likely to be read to every day (59% versus 68%). Conversely, in households with strict rules regarding television exposure, children watch less television and spend more time reading.

Partly in response to this change in the media landscape, the American Academy of Pediatrics (1999) recommended that parents not expose children under the age of 2 to any type of screen media and that they limit screen time to 1 to 2 hours per day for all screen media, including computers, for children over the age

of 2. This recommendation was based on two major concerns. First, numerous studies had shown negative effects of media aggression on preschoolers' behavior, and it was predicted that such effects would also occur when exposure occurred at a younger age. Second, time spent with screen media may displace other activities that are more important for children's development, such as face-to-face time with parents and caregivers. The finding that being read to occurred less in heavy-television households is consistent with this hypothesis.

ATTENTION AND LEARNING

Attention

Anderson and his colleagues have examined the development of attention to television during early childhood. Children's visual attention to television increases as a function of age. In observational studies, 1-year-olds begin to attend to the television, and by 2.5 years of age children sit facing the television set and glance at it more frequently and for longer durations. A number of salient formal features consistently increase toddlers' and preschoolers' attention to television. Attention to televised content increases and remains high in the presence of female adults, character action, children, puppets, animation, active movement (including dancing and repetition), singing and lively music, peculiar voices, and sound effects. It decreases when the length of a segment increases, during low action, and during periods of adult narration or abstract adult dialogue. Increased attention in the presence of a salient effect has also been associated with increased comprehension of the media content by young children. Other forms of attention, such as online verbal and nonverbal imitative behavior, pointing, and verbalizations, have also been associated with increased comprehension.

Imitation

Historically, researchers chose imitation to investigate the potential impact of television exposure because it provided a direct measure of knowledge transfer in an ecologically valid manner. Successful completion of the imitation task from a videotaped model requires participants to form a memory of the event on television and to transfer that memory to 3-D objects in the real world. In Albert Bandura's classic studies, 3-to 5-year-old children watched as an adult modeled a number of novel, aggressive acts using an inflatable Bobo doll. Children who were exposed to the televised adult model exhibited high levels of aggressive behavior toward the doll when they were allowed to play with it immediately after the demonstration. Furthermore, children were as likely to imitate aggressive acts modeled on television as they were to imitate such acts when they were modeled live.

More recently, the ability of preverbal and early-verbal infants to learn from televised presentations has also been examined using imitation studies. Initial studies have shown that 14-to-15-month-olds can imitate limited actions demonstrated by videotaped models. A videotaped demonstration has also been shown to be an effective reminder for 18 months for events they learned 10 weeks earlier.

BENEFITS AND RISKS OF TELEVISION EXPOSURE

Infants and toddlers are currently being exposed to relatively high levels of television, and the long-term impact of such exposure is currently not known. Although parents are being told to avoid exposing their infants to screen media, they may also feel pressures to ensure that their children are media literate.

Possible Benefits

The Effect of Repetition on Learning From Television

Infants often see material repeatedly because of television programming content and video technology. Parents report that preschoolers frequently ask to view the same program repeatedly. Furthermore, with repeated presentations of the same television program, preschoolers' attention is maintained, while comprehension increases until it finally reaches a ceiling. When televised demonstrations are repeated, even infants as young as 6 months can imitate simple actions from television. Furthermore, vocabulary gains from television viewing were seen in a longitudinal study when infants repeatedly viewed *Sesame Street* videos or DVDs but were not seen when they viewed television programs. These findings have important applied implications for television programmers. For this reason, programs such as *Blue's Clues* are aired multiple times per week.

Language Development, Learning, and Academic Success

There are beneficial effects of screen media for children as young as age 2. For example, exposure to high-quality children's educational programs such as *Sesame Street* and *Mr. Rogers' Neighborhood* during the preschool years have enhanced cognitive development, language development, and prosocial skills, and they have a long-lasting, positive impact on school readiness and academic performance.

Possible Risks

Infants may be at risk from exposure to television because they are often exposed to content that is designed for an older audience, or *background television*. Very young children overtly attend to *foreground programming* because it is designed for their age group and often includes some educational content. In contrast, background TV programming is not created for children, and its content is incomprehensible to them. Most infant and toddler exposure to media comes when other family members are using media.

Effects on Play and Family Interaction

Exposure to background television interrupts the duration of play bouts in 1-year-olds. Furthermore, during background television exposure, parents and caregivers attend to television content and reduce their interactions with children. Therefore, background television may interfere with learning on two fronts: by decreasing parent-child interaction and also by disrupting focus on play via incidental sound effects that attract infants' attention to television and away from ongoing play for short periods of time. Reorienting to play is difficult, and it is more difficult because there is not parental support to do so. Quality of play is disrupted by background television and is another example of displacement that occurs with media exposure.

Attention Problems

Heavy exposure to background television has also been associated with subsequent attention problems. Christakis and colleagues asked parents to report how many hours the television was on per day when children were 1 and 3 years old. When children were 7 years old, parents completed a seven-item attention problem index. In households with heavy television use, parents reported that 7-year-olds had higher scores on the attention problems index. The study included a large sample and controlled for multiple potential risk factors, including differences in socioeconomic status, maternal risk factors such as maternal depression, and child risk factors such as prematurity or prenatal drug exposure. However, there were limitations to the study. Although is it possible that early TV viewing causes later attention disorders, it is also possible that children with attention disorders are motivated to watch more television or are encouraged to do so by parents who find it difficult to cope with high levels of hyperactivity or poor attention.

The Video Deficit Effect

The term *video deficit effect* refers to the finding from multiple paradigms—including imitation tasks, object search tasks, emotion processing tasks, and verbal comprehension tasks—that, prior to age 3, children have difficulty transferring what they view on screen to real life and consistently learn less from television than from a live demonstration.

INFORMATION PROCESSING, ACTIVE VS. PASSIVE MODELS OF

Although we may believe that we do the majority of our information processing—from watching ads and television shows to shopping and voting—in a very active, rational way, numerous *dual-process* models and theories developed in the fields of communication, marketing, and social psychology demonstrate how we often take in and use information passively, perhaps even without our awareness. Developmental psychologists have recently demonstrated that this can be especially true of children and adolescents, suggesting that mass media may subtly but profoundly persuade them and that they are more likely than adults to judge and act without considering the consequences. Due to personal differences and depending on the situation, we are sometimes prone to simply “absorbing” new information that we may use in making judgments and decisions—even if we are unwilling or unable to express our reasons for believing or behaving as we do.

Active and passive models, including those of impression formation, persuasion, judgment, and decision making, represent the purest forms in dual-processing theories. Early in their history, dating back to the mid-1970s, the active and passive thinking modes were seen as distinct types—that is, it was assumed that at times we do either one or the other. However, more modern versions define them as continuum endpoints, suggesting we usually perform *mixed processing*—some combination of the two. However, most theories are still somewhat vague in explaining how the processes co-occur.

Various theories examine different dual-processing categories, and debate about the models persists among researchers—for example, between proponents of the elaboration likelihood and heuristic-systematic models. As theories of persuasion, these involve the ways in which we receive information from media—gaining knowledge and forming attitudes and opinions—but other theories describe the ways we use the information we get in making decisions. Nevertheless, all such theories argue that there are at least two routes (and, by definition, not just one) by which we receive and use information. Although most theories describe both an active process and a passive one, there is generally at least an underlying assumption that the two opposites represent ends of a continuum and that we often use “mixed processes,” or a combination of the two routes. All the theories also agree on the criteria that determine whether we will process (more) actively or passively: *motivation* and *opportunity.*

Motivation refers to our desire to think carefully, based on whether we imagine something is important or not, and we can be motivated from within or by our environment. For instance, children may be motivated to come up with a good reason for their parents to buy them the toy they want, either because they like it or because “all the other kids have it.” *Opportunity* includes mental and physical resources. Due to “limited cognitive capacity”—meaning that most of us can actively think about seven plus or minus two pieces of information at a time—we sometimes become “loaded down” and unable to think about important things. We may also find ourselves “strapped for time” and unable to actively read or make a decision. Dual-process theories suggest that we actively process only when we have ample motivation and opportunity: as “cognitive misers,” without the ambition or resources to process actively, we default to passivity.

Given the enormous amount of information we encounter in daily life, many argue that most of our processing is done rather passively, especially among children. Potential negative consequences of such passive information consumption and use include stereotyping, prejudice, and increased consumerism, and passive processing may also help explain how media violence makes hostility seem normal. However, such subtle persuasion has also been shown to have potential benefits, such as creating stronger anti-drug attitudes among youth.

INFORMATION PROCESSING, DEVELOPMENTAL DIFFERENCES AND

Children and adolescents use a variety of media, including computers and the Internet, video games, print media, movies, videotapes and DVDs, music, and television. Even as the media landscape expands, television has maintained its place as the most commonly used medium and is the focus of most studies of information processing of media and developmental differences in these processes. Three general areas are of particular interest: attention to television, comprehension of and memory for televised material, and long-term learning of educational content.

ATTENTION

Popular conceptions of television viewing often characterize children as "zombies" staring fixedly at the television, but naturalistic and laboratory studies of how children watch television typically contradict this stereotype. Instead, infants, children, and adults all show similar patterns of looking at and away from television; most looks are very short (less than 3 seconds), with only occasional extended looks at the television. This consistent pattern does not mean that attention is unchanging across development. The percentage of time children spend looking at television at home or in the laboratory increases steadily from infancy through middle school, finally leveling off during adolescence. Children typically divide attention between television and other activities, with increases in percentage of attention to television largely due to more time spent in longer looks by older viewers. In turn, such long looks appear to enable greater engagement and deeper processing of content, as viewers are less distractible and remember more content presented during long looks.

What drives these patterns of attention? The very youngest viewers, infants and toddlers, are exposed mainly to television not designed for them. They may process little content but primarily react to the changing sights and sounds of television. By as early as 1 1/2 to 2 years of age, however, children begin to respond more systematically to features that are not merely salient but signal content that children are likely to find relevant or entertaining. For example, the presence of children's voices, peculiar voices, sound effects, animation, and puppets cue children to the child relevance of the content. Across the preschool years, children's ongoing comprehension increasingly influences their attention. If children make sense of a program and judge it to be "for them," they are more likely to sustain attention than if the program seems confusing or adult oriented.

COMPREHENSION AND MEMORY

There has been little assessment of comprehension of and memory for television and video in infants and toddlers, with most studies focusing on imitation of simple action sequences and retrieval of objects from locations illustrated on video. In general, very young children learn less when guided by video than they do from live displays, although children's performance improves with repeated viewing. Even for preschoolers and young elementary school children, it often is asserted that children make little sense of most programs because they are poor at selecting important events, connecting events, and inferring causes of events. However, preschool children are able to understand relatively

complex stories if plots hinge on concrete action sequences, if dialogue and action are well integrated, and if story events relate to children's experiences.

To comprehend a televised story, one must understand information that is conveyed by production techniques. For example, a viewer must infer that a shot of a house's exterior followed by a shot of characters seated in a living room conveys the location of the characters within the house. Young children are capable of making such inferences if they concern simple relations in time and space. A second requirement for effective comprehension is appreciating that not all story events are equally important to the plot. Some of the most important events are those that can be connected as causes or consequences of other events. Diverging from claims that young children are unselective and insensitive to such connections, events with many connections are remembered best as early as the preschool years.

There is, of course, considerable development in comprehension skills during middle childhood and adolescence. Not until later in elementary school do children become consistent in understanding complex production techniques (e.g., flashbacks) and characters' emotions, intentions, and motivations. Older children and teens also become more skilled at connecting groups of events to an overall theme. With age, children add to their stores of world knowledge and so become capable of appreciating a wider variety of situations. Similar patterns of development of comprehension skills are observed for stories presented via different media.

LEARNING FROM EDUCATIONAL TELEVISION

The research on children's comprehension and memory for television is predictive of conditions for learning from educational television. Until recently, little educational television has been directed to children under 2 years of age. Several studies focusing on overall levels of infants' and toddlers' television exposure suggest negative effects on cognitive development, but limited evidence suggests that viewing of specific programs contributes positively to very young children's vocabulary development. For preschoolers, more extensive evidence indicates that television programs with clear curricular goals that are informed by research on young children's attention and comprehension (e.g., *Sesame Street*, *Blue's Clues*, and *Dora the Explorer*) produce both short-term and long-term positive impact on school readiness, vocabulary development, literacy, problem solving, and flexible thinking. For older children, one of the challenges to successful educational programming is the need for a compelling narrative structure to maintain children's interest while keeping educational content centrally linked to the narrative. Shalom Fisch has proposed that the limited capacity of working memory constrains the amount and depth of processing that can occur simultaneously for narrative and educational content. According to this model, if resources allocated to narrative processing diminish those available for processing of educational content, educational goals are unlikely to be met. Conversely, to the extent that educational content is integrated with the causal structure of the narrative, the more likely the educational content is to receive deeper processing. With development, increases in speed of processing, world knowledge, story schemas, inferencing abilities, and knowledge of television conventions enable older children to benefit from programming that incorporates complex goals.

INSTANT MESSAGING

Instant messaging, also known as IM, is an instantaneous textual communication technology that is free to anyone who has an Internet account and is able to download it. Primarily offered through large Internet service providers and computer conglomerates such as AOL, Microsoft, Yahoo, and Google, the instant messaging tool appears on a computer monitor looking like a box with a list of log-in names (a "buddy list") and an indication of whether the person who uses the log-in is online and available to chat at the moment. Often, adolescents will hold several conversations with several different people at the same time.

With Internet usage growing steadily among the general population, adolescents in particular have seized upon the medium to play games, conduct research for homework, download music, shop, read news, and especially to socialize with other teens, both close friends and strangers, often controlling and managing an entire social world in doing so. Nearly nine out of ten American teens are now online, and 72% do so primarily to use instant messaging. The AOL/DMS study confirms that, if teens had to choose to give up one thing in their lives forever, 25% said they would miss instant messaging or emailing with friends and family the most.

Children and adolescents who use instant messaging often appear to employ a language of their own when conversing with one another. These may include simple abbreviations (*gtg* for "got to go," *brb* for "be right back") but also include playfulness with the language (holding down keys for emphasis, as in "pleeeeeeeeeeeeeeeeeeeeeeeeeeeeeeease!"), reliance on visuals and multimedia (inserting photos of actresses, links to fun websites, or audio clips into their conversations) and often with adolescents, profanity (general swearing but also abbreviations such as *wtf* for "what the f—"). Adults who read IM conversations between children and adolescents often complain that they need a glossary to understand them, which, according to some teens and tweens, is the point. They view instant messaging as a space where they can carry on conversations and experiment with adult tones without parents and teachers actually hearing them.

Past computer-mediated communication research indicates that adults often "play" with identity, sometimes taking on a different gender or a more fantastical nature. However, most research on children and adolescents in instant messaging demonstrates that users often maintain an identity consistent with their real-world identities. Although they experimented with different tones, voices, and subject content among the different persons with whom they communicated, they generally adhered to a consistent presentation of self to acquaintances.

Online identity construction and negotiation appear to be major considerations in this communication process among adolescents. Negotiation is often located directly through the discourse of online communication—specifically, through language use, social networking, and power negotiation among peers, as well as general surveillance of the social online landscape. Identity may be articulated in various ways within instant messaging, including through the choice of a log-in name (such as sexysexygrrl or vball22) and the way users describe themselves in their public profile that is associated with their log-in names, but it also is constructed through the words and symbols users type and insert in any conversation. Often, instant messaging is a space where aggression is easy to act out without consequence—for example, bullying classmates or

fighting with others with a barrage of mean messages, swearing—so an adolescent may construct him- or herself as tougher than in real life. It is also a space in which many experiment with sexuality, from small acts of flirting to planning and discussing actual sexual encounters with others. Sexual harassment also has found another venue within instant messaging. And even though those using IM are doing so without the trappings of a body and the preconceived notions of gender, patriarchal discourses that often pigeonhole boys into conversing in ways that they perceive as masculine and girls into taking on feminized roles in the conversation still seep into the online landscape.

Furthermore, because instant messaging is deployed by large corporations and conglomerates, it is not a commercial-free environment. AIM (from AOL) launches a screen with a few of the day's headlines and links to AOL's advertorial each time a user logs in to its IM system; both AIM and MSN Messenger (Microsoft's IM system) place rotating banner advertisements within their IM boxes. Furthermore, companies have developed "bots"—artificial intelligence-powered computer programs that appear to chat with users as if they were live human beings—that users may add to their buddy lists, and they may converse with these bots about specific products that are often youth oriented.

Instant messaging blurs the public and private spheres in ways that were not possible with traditional communication. While users converse in one-on-one dialogue with each other most of the time (it is also possible to use a chat room or to converse with three or four people in the same window at once, but it is less common), they may carry on many one-on-one conversations at once. Furthermore, younger IM users often copy and paste pieces of a one-on-one conversation into conversations with others; sometimes this acts as a means of validation ("did he really say that about me?" "yes— here's what he just wrote:") or a means of spreading rumors or passing along humorous conversations. Sometimes, these pasted pieces of conversations are passed among members of an entire peer group or even among all students in an entire school, which makes IM a space where mass communication is easily possible and where privacy is truly an illusion.

INTERACTIVE MEDIA

One of the most important assets of the media environment that children and adolescents face today is the mass availability of interactive media. Driven by advances in computer technology, a variety of communication tools and platforms have emerged that allow users to manipulate the content and form of communication (within certain limitations) and to participate actively in using the media product. Thus, interactive media offer greater freedom and more variability, flexibility, control, and influence in communication choices and behavior than conventional noninteractive, "linear" media. Nevertheless, use of linear media has always been personalized and somewhat interactive. For instance, readers of a newspaper can choose which articles they want to read, and VCR owners can fast-forward or rewind a movie to break up its linear structure. The new feature of interactive media is the opportunity for each user to construct and

modify media content and form actively, in both mass and interpersonal communication. This entry examines the values and the risks associated with the interactivity of three prominent media of today: the Internet, video games, and mobile phones.

THE INTERNET

One may think of the Internet as the most important interactive medium in the Western world and Asia. Although it is not a medium in itself, the Internet unifies various tools for mass and interpersonal communication. The World Wide Web (WWW) is the most relevant mode of interactive mass communication. Through the WWW, users can actively select information from an abundance of sources and establish their own personal communication platforms (home pages). Moreover, WWW users interactively can publish, search for, and receive digitized media products, such as music files, movies, and pictures. The WWW also allows many users to generate media content collaboratively, for instance, in online lexica such as *Wikipedia*.

The Internet also offers various systems for computer-mediated interpersonal (one-to-one and one-to-many) communication. Email and chat rooms mirror traditional communication modes (handwritten letters and personal conversation, respectively), and instant messaging services allow users to set up whole peer groups online for continuous exchange. Each of these interactive tools offers certain advantages for communication (e.g., availability, speed, convenience), but each also involves specific limitations (e.g., a lack of nonverbal cues that could prevent misunderstandings).

VIDEO GAMES

Also referred to as *computer games*, *electronic games*, or *digital games*, video games represent the most sophisticated interactive media technology available for home markets today. Video games exploit computing technology to create entertainment experiences. A game simulates a specific "world" and assigns to players a certain role within this world, for instance, the role of wizard, soldier, or household head (e.g., *The Sims*). Interactivity allows for participation in and co-creation of the game world, for instance, by exploration, competition, construction, or object collection. A narrative framework integrates players' actions into a story plot and adds to the overwhelming appeal that video games have for many (primarily male) children and adolescents.

MOBILE PHONES

The third important interactive medium available to adolescents (and, to an increasing degree, children as well) is the mobile phone. Mobile phones have become adolescents' favorite channel of conversation, especially in Europe. Equipped with additional devices such as cameras, organizers, music players, and video game applications, modern cellular phones serve as personal "life managers" that offer multimedia communication and entertainment. The most important feature of cell phones that explains their tremendous popularity among young users has always been, however, SMS (short message service). With SMS, a brief message is input into a cell phone and transmitted to (at least) one other person's cell phone. Without requiring both conversation partners to be available synchronously, SMS connects users ubiquitously, discreetly, and—given most users' remarkable command of an SMS-specific language with many abbreviations—efficiently.

THE VALUE OF INTERACTIVE MEDIA TO ADOLESCENTS

The features commonly referred to as *interactivity* have boosted the mass distribution of various new media technologies, especially among children and adolescents. A developmental perspective would attribute the success of interactive media to the observation that interactive media serve various needs that are highly salient for young people.

One such need is play or entertainment. Interactive video games create fascinating, exciting, and manifold experiences of play and enjoyment. The creation, maintenance, and actualization of peer relations is another important need, especially in adolescence. Interactive media such as SMS fulfill this requirement conveniently and effectively. For another example, online dating services are controllable (i.e., anonymous and "secure") ways to "meet" new potential partners and free users from the pressure of self-disclosure and other uncomfortable experiences that come along with face-to-face dating. Therefore, interactive media powerfully assist adolescents in maintaining existing and establishing new social relationships.

The development of interpersonal identity is an important part of young people's experience and

relates to their needs for play and for relationship management. By using interactive media, adolescents can experiment with different social roles, try out alternative social behaviors, and get feedback about them. Online communities such as chat rooms are excellent stages for such identity play and allow young users to learn about themselves.

THE RISKS OF INTERACTIVE MEDIA

The mere capacity of interactive media to help children and adolescents fulfill certain needs does not mean that interactive media are necessarily valuable and positive factors in young people's development. Heavy reliance on Internet-based communication (as opposed to face-to-face conversation) may impose the risk of social exclusion, harmful social experiences, deprivation of social-experiential diversity, and other potentially problematic consequences. Similar concerns have been raised with respect to massive video game exposure (e.g., increase of aggression, risk of childhood obesity).

CONCLUSION

There is no doubt that interactive media will keep and even expand their dominant role in children and adolescents' media environment. Young people display remarkable energy and speed in adapting to interactive media, and they quickly learn how to utilize these media for their needs. The numerous advantages interactive media have to offer, however, may also imply serious dangers to positive development, specifically when young users consider these media a full replacement for, rather than a useful complement of, conventional media of interpersonal networking and entertainment.

INTERACTIVITY

The media environment in which children and young people are now participating has become increasingly characterized by interactivity. *Interactivity* refers to the condition of communication in which simultaneous and continuous exchange occurs, and which involves some form of media or information and communication technology. Interactivity is an attribute of face-to-face conversation, but in relation to media it is often associated with new media, which increasingly blur the distinction between users and producers. In contrast, more established technologies are based on a one-way, mass and noninteractive communication.

Sally J. McMillan distinguishes between three types of interactivity: interaction between users, interaction between users and documents, and interaction between users and systems. The last is a variety of human-machine interfaces, for example, search engines, conversational computer programs, and computer games.

THE PROMISE OF INTERACTIVITY

The interactivity of the new media has been often regarded as potentially empowering for children, as democratizing, and as challenging centralized control. Interactivity enables greater command of the communication process by allowing users to modify the form and content of a mediated environment in real time. For instance, many children's television programs use input from the viewers, and they encourage kids to create content and send it by media such as email or instant messaging.

Because of their interactive character, new media are often seen as more democratic than the hierarchical media that preceded them. The new media enable children and young people to become cultural producers in their own right and so to evade the control of their parents. By interacting with other users (for example, through online chat), with documents (for example, with hypertext), or systems (for example, in virtual games) children can play roles that they are not allowed in real life. As surveys have shown, children and teens use the Internet to look for information, and they interact in online forums about health topics that perhaps are difficult to talk about, such as drug use, sexual health, or depression.

Interactive multimedia liberate their users from the constraints of more traditional linear media such as film and television. They abolish the distinction between reader and writer, consumer and producer. Writers such as Douglas Rushkoff and Don Tapscott claim that the interactivity of the new media empowers young people in that they can refuse to buy into the role of the passive viewer who obeys linear programming such as television. These writers regard interactive media forms as increasing consumer choice for young audiences and as offering them new means of learning.

There is great optimism about the potential of interactivity for schooling and education. Studies show that the introduction of interactive media into the curriculum can potentially enhance collaboration and cooperation, responsibility, satisfaction, learning and mastery, knowledge and understanding of the world, language development, motivation to engage in an activity, and sociability.

THE LIMITATIONS AND DANGERS OF INTERACTIVITY

As David Buckingham observes, enthusiasts' arguments offer a powerful challenge to the common stigmatization of young people as "dupes" who passively consume all-powerful media. However, despite the appeal and potential benefits for children and adolescents, interactivity has crucial limitations and may not always have positive outcomes.

First, the safety of children and young people using interactive media such as the Internet is far less easy to secure. Its use is more difficult to control and supervise than use of the noninteractive media. Although the interactivity of the new media enables children to exert more influence on the content and form of the communication, they are more open to dangers beyond their control. For example, incidents of adult sex offenders meeting children in interactive online forums and gaining their trust are increasing in both the United Kingdom and the United States.

Second, enthusiasm about the democratizing potential of interactive media might be also tempered by data on increasing surveillance of consumer behavior and of young people's use of new media in particular. There is growing unease over the use of interactivity by online advertisers, particularly with regard to unfair or deceptive practices that target children and teenagers and may violate children's rights and privacy.

Third, that children interact with numbers of sources does not necessarily mean that they enjoy greater diversity and freedom of choice. The increasing commodification and convergence of the media in general and the Web in particular (for example, the growing control of the Internet and child-related online sites by large corporations such as TimeWarner and Disney) constitute a real threat to the promise of children's participation in an interactive, truly diverse and multicultural media environment.

In the context of schooling and education, Buckingham notes that the positive aspects of interactivity should be tempered by declining state investment, growing involvement of commercial corporations in educational interactive software, and increasing pressure on parents to compensate for the failings of public education. Furthermore, studies have shown that interactive software introduced into schools often fails to meet the promise of greater control by the learner.

Lastly, users may perceive a communication setting as interactive and affording opportunities to participate even though they may not have control over, or reciprocity with, the sender or system. Many texts that describe themselves as interactive offer a rather conventional, fixed, and very limited repertoire of possibilities. It is also important to remember that,

currently, the creative, educational, and communicative benefits of interactivity in new media such as the Internet, educational software, and computer games, are realized by only a small elite.

On a more general note, Erik P. Bucy notes that the underlying assumption of most interactivity research is that two-way communication is categorically desirable and associated with positive outcomes. It would be useful to question this assumption and examine it empirically in relation to children's and young people's experiences of media, as well as those of adults.

INTERNATIONAL CLEARINGHOUSE ON CHILDREN, YOUTH, AND MEDIA

In discussions during the 1990s, a number of researchers and activists around the world called attention to the importance of establishing an international center for knowledge of children and media, with special emphasis on media violence. UNESCO and the Swedish government showed particular interest in carrying the question further. In 1997, Nordicom (the Nordic Information Centre for Media and Communication Research) at Göteborg University in Sweden was asked to take responsibility for the establishment of the UNESCO International Clearinghouse on Children and Violence on the Screen. The work of the Clearinghouse has increasingly focused on communicating scientific knowledge about young people and the media from a variety of perspectives, and in 2002 the center's name was changed to the International Clearinghouse on Children, Youth, and Media.

The aim of the Clearinghouse is to increase awareness and knowledge about young people and media, thereby providing a basis for relevant policy making, contributing to a constructive public debate, and enhancing young people's media literacy and media competence. Moreover, it is hoped that the Clearinghouse's work will stimulate further research on children, youth, and media.

The Clearinghouse is a knowledge center for various groups of users around the world, including researchers, policymakers, media professionals, voluntary organizations, teachers, students, and interested individuals. A central idea behind the Clearinghouse's activities is the establishment of an active global network. Interest in the network has continuously increased, and today there are 900 participantsrepresenting a number of different users. More than 125 countries from all continents are represented in the network.

Books, reports, and a newsletter are published by the Clearinghouse. One of the most important tasks is the publication of a yearbook. The yearbooks contain articles focusing on one or two current themes and written by qualified scholars from different regions of the world. These themes included media violence, media education and literacy, young people's participation in the media, video and computer games, pornography and sex in the media, media globalization, media regulations, soap operas and reality television, democracy, and public service. The learinghouse also regularly releases a newsletter, which contains brief articles, news items, presentation of new literature, recent conferences, and more. The newsletter, which is available on the group's website, has 2,000 subscribers in 150 countries.

The Clearinghouse's website contains information on publications, current and archived newsletters in full, a literature database on media violence, and a database on relevant institutions and networks in the world, as well as international declarations and

resolutions concerning young people and media. Moreover, information about international coming events is continuously added to the home page. Another resource is a special themes database, which makes it possible to locate articles from Clearinghouse publications classified by specific themes.

From the start, organizers of international and regional events addressing young people and media have asked the Clearinghouse for formal and informal advice before and during such programs. These groups include UNESCO, UNICEF, the European Union, the World Summits on Media for Children and Adolescents, the International Association for Media and Communication Research, the International Center of Films for Children and Young People, the Children's Broadcasting Foundation in Africa, the International Forum on Children and Media, and the Asian Media and Communication Centre.

The activities of the International Clearinghouse on Children, Youth, and Media are financed by the Swedish government and UNESCO.

INTERNET BLOCKING

Children's use of the Internet confronts parents with two broad issues of control. One has to do with the content youngsters bring into the house purposefully or accidentally through their online connections. The other involves sensitive information children might reveal about themselves and their families when they respond knowingly or unknowingly to online questions. With youngsters across a gamut of ages using the Internet, many U.S. parents find themselves with conflicting attitudes. They recognize the technology's benefits for their children, but they worry about the violent, sexual, or stereotypical depictions to which Internet predators may expose their children, and they are concerned about unscrupulous actors who may try to obtain information regarding their children and families. Parents can respond to these concerns through nontechnological means such as rules for computer use and by using technologies such as monitoring programs and Internet filters.

PRIVACY CONCERNS

Both the issue of objectionable content and the concern with sharing personal information raise questions about privacy. The extent to which these issues are contentious varies across societies as well as within them. In the United States, legislative, business, and advocacy groups have accepted the importance of considering the nature of incoming and outgoing material when children make up the online audience. They broadly agree that two key privacy rights are involved. The first involves the right to be left alone—that children should not be bothered by potentially exploitative material—and the second asserts the right to control one's personal information. Nevertheless, legislative, business, and advocacy groups do not always agree on what incoming or outgoing material is unacceptable for what age of children, how it should be blocked, or who should take responsibility for blocking it.

Digital interactive technologies are increasingly playing a central role in the lives of children and young people in the United States. A Kaiser Family Foundation study found that, in 2004, 74% of children aged 8 to 18 were living in homes with available Internet access, compared to only 47% of children in 1999 (Roberts, Foehr, & Rideout, 2005). The Pew Internet & American Life Project found that, in 2004, approximately 11 million teens (aged 12 to 17) went online daily, compared to about 7 million in the year 2000 (Lenhart, 2005).

A 1999 nationwide survey conducted by Turow of parental attitudes toward the Web noted the tension between the potential value of the Internet and the dangers it can present for child users. The survey found that 70% of parents with computers in the home said that the Internet is a place for children to discover "fascinating, useful things," and nearly 60% said that children who did not have Internet access were disadvantaged compared to their peers who did. At the same time, more than 75% of parents expressed concern that their children might give out personal information and view sexually explicit images on the Internet. Subsequent studies note that parents' conflicted vision of the Web for their children continues. Many of these hopes and fears reflect a desire to

properly calibrate the permeable boundaries between the family and the world outside it, particularly when it comes to the protection and socialization of children.

STRATEGIES FOR PROTECTING CHILDREN

Nontechnological Approaches

Web experts and children's advocates suggest technological and nontechnological strategies parents can use to protect their children when they go online. Nontechnological strategies that aim to "block" undesirable incoming and outgoing activities include placing the computer in a public location in the home (not in the child's bedroom), implementing rules regarding usage, discussing appropriate usage with child, and checking up on what their child is doing and where they are visiting online. Technological strategies for blocking involve filtering and monitoring of the children's Internet use.

Monitoring Technology

Monitoring technology involves software programs that track, secretly or openly, where child users go on the Internet and what they do when they get there. This technology does not provide parents with a way to determine whether objectionable material was sought out or was accidentally discovered. Those who despise the idea of monitors argue that is a repugnant form of eavesdropping. Those who advocate the practice argue that parents have a right to review what their children do online. In particular, they say, making youngsters aware they are being monitored is akin to having a parent standing behind them and will encourage Internet activities that mesh with their family's values. Moreover, they say, monitors allow for a fuller use of the Internet than filters do.

Internet Filters

Filters allow Internet users to view certain content while blocking other online content. A filter can come in the form of a software program that is purchased and installed on a computer. It may be offered from the user's Internet service provider (ISP), or parents can pay to have their Internet access routed through a filtering company. Filters can be customized by their users in different ways. Some filters use a "blacklist" of website addresses that are inaccessible to the users; others create a more restrictive "whitelist" of website addresses that may be visited and block access to all others. Additionally, some filters scan websites for objectionable content in the form of text and images. Finally, some filters work with website rating systems to determine what websites are and are not appropriate.

Many parental advisors have advocated the use of filters, and the Children's Internet Protection Act (CIPA) requires libraries or schools that want government discounts for Internet access to place filters on the Internet computers used by children. Naysayers point out, however, that filters may work against useful child exploration. For example, gay and lesbian advocates contend that filters typically make it impossible for youths concerned about their sexuality to find websites expressing similar feelings, from which they can then learn. Those who dislike filters also note that they may inadvertently eliminate parts of the Web that may be useful or informative to children in connection with their schoolwork. The word *breasts*, for example, may launch the filtering of sites that could discuss important aspects of breast cancer, breast reconstruction, or even teen angst about breast size. Advocates of filters counter that technology is improving, with more sophisticated filters that look for words or phrases in certain contexts. For example, a filter would allow the word *breast* when preceded by *chicken* or followed by *cancer*.

Most large Internet service providers offer filters for parents who want to use them, yet nearly half of all parents (46%) acknowledge that they do not implement this technology (Lenhart, 2005). Recent data suggest that filter implementation is related to parental Internet use. Specifically, only 38% of parents who do not go on the Internet themselves say they filter Internet access for their children, compared with 56% of online parents (Lenhart, 2005). Many parents with basic computer and Internet skills often do not feel comfortable using filters (Turow, 1999), which possibly explains the discrepancy between Internet and non-Internet-using parents. The difficulty of implementing blocking technology is compounded for parents of adolescents because adolescents are often able to find ways to circumvent the limits placed upon them, including simply going to a friend's home where the technology does not exist. This expectation that teens will circumvent the system may help explain why 49% of families with older teen users aged 15 to 17 report using filters compared with 60% of families with younger teen users aged 12 to 14 (Lenhart, 2005).

Just as blocking objectionable online material using technologies comes with an age continuum, so are nontechnological approaches age related. Research shows that parents implement these practices much more with younger children than with older teen users of the Internet. For example, according to a study by Amanda Lenhart (2005), 75% of families with children aged 12 to 14 report having have rules regarding Internet use, compared to 55% of families with children aged 15 to 17. Further, 70% of parents of children aged 12 to 14 say they have followed up on their child's Internet behavior, compared with only 55% of parents of teens aged 15 to 17.

THE CHILDREN'S ONLINE PRIVACY PROTECTION ACT

When it comes to blocking youngsters from sending sensitive personal information out of the home, the federal government has joined in through the Children's Online Privacy Protection Act (COPPA), which went into effect in April 2000. The act was developed as a result of parents' concerns that their children may give up information that would identify them to strangers on the Internet. It applies to the online collection of personal information from children under the age of 13 and clearly details what a website operator must include in the privacy policy, when and how to seek consent from a parent, and what responsibilities the operator has to protect children's privacy and safety online (U.S. Federal Trade Commission, 1999). Early research showed that websites required to follow COPPA often "did not live up to the spirit and sometimes even the letter behind the rules" (Turow, 2001, p. 2). In recent years, the U.S. Federal Trade Commission (2002) has found better compliance.

Perhaps as important as compliance with COPPA is the act's definition of the ages at which children are considered vulnerable online. As the result of political pressures from marketers, COPPA clearly identifies children under the age of 13 as those needing protection and forgoes any discussion of older teen users. Parents' tendency to use technological and nontechnological blocking parallels this age distinction. These findings are ironic when one considers that, the older children get, the more time they spend online, the more skilled they become at using the Internet, and the more opportunities and risks they experience. In fact, around 60% of parents in two national surveys reported by Turow and Nir (2000) and Turow (2003) said they are more concerned that teenagers, rather than children under 13, may disclose personal information to a website.

POLICIES FOR THE FUTURE

The era of digital interactive technology has only just begun. The notion of a discrete "Web" in the home is likely to blur as interactive digital television, radio, Internet, cell phones, video games, and print materials become common via broadband. Arguments about and uses of these new forms need to be tracked and benchmarked. Academics should engage in cross-cultural research that explores different definitions of and social arguments about media privacy in different societies. One key goal should be to explore the best mix of governmental, industrial, parental, and child-based strategies for addressing concerns about digital interactive technologies that youngsters use during the 21st century.

INTERNET BULLETIN BOARDS

Bulletin boards or message boards (including precursor technologies such as Usenet) are online spaces where Internet users can gather and discuss topics of mutual interest. Bulletin boards are sometimes grouped with chat rooms; however, chat room conversations take place in real time and tend not to be stored, so chat room discussions tend to be more social and less informational than conversations on bulletin boards. Because an increasing number of websites, from shopping sites to photo-sharing sites and personal home pages, include the opportunity for visitors to comment, the boundaries of what should be considered a bulletin board have begun to blur, and studies of the bulletin board as a separate "genre" are declining.

The variety of subject matter discussed on Internet bulletin boards is almost limitless, and the potential harms and benefits for young people are similarly diverse. Bulletin boards have been praised as a way to allow young people to participate politically with greater equality and as a way for them to overcome shyness and share experiences. They have also been noted as a means to "de-stigmatize" membership in groups with marginalized identities, which can be seen as good or bad depending on whether one believes that the identity in question *should* be marginalized.

USAGE

In 2004, a large-scale survey in the United Kingdom of 12-to-19-year-old regular Internet users found that 17% contributed to bulletin boards, whereas a Pew survey conducted in the United States in 2000 found that 38% of 12-to-17-year-olds go to websites and bulletin boards to express their opinions. Little is known about how these young people might differ from young online users who do not use bulletin boards, although the UK study did find that young people who posted messages on bulletin boards were more likely to be middle class and older than those who did not. Statistics on participation in bulletin boards overall are not readily available and can be hard to compare, as surveys of Internet use now tend to ask about site use by subject (e.g., "Have you visited sites about health?") rather than by site type (asking whether the user has visited "static" informational sites about health vs. bulletin boards on health). What constitutes use is also problematic, as some studies focus on active participation (i.e., people who post messages to bulletin boards), whereas a large proportion of bulletin board users rarely or never post messages themselves.

It seems likely that young people visit bulletin boards that relate both to broad interest categories available to everyone (sports, cars, etc.) and to traditional youth interests (e.g., music). It is possible that, because young people are still experimenting with and coming to terms with their identities, they may be disproportionately interested in bulletin boards that discuss issues that are difficult to raise face-to-face.

POTENTIAL BENEFITS OF BULLETIN BOARD USE

Self-Disclosure and Health

A number of medical researchers and social scientists have suggested that participation in online bulletin boards where the chronically ill can share their experiences can help sufferers cope more effectively with their diseases, both through information sharing and through the provision of emotional support.

Political Participation

E-democracy advocates were among the early researchers of bulletin board use. Because many bulletin boards permitted anonymous or pseudonymous participation in political discussions that spanned the globe, it was thought they could help to enable more equal participation by geographically dispersed groups and, crucially, by people of low social status (young people among them) who might be intimidated by face-to-face gatherings. Bulletin boards for political consultation have been discussed as ways to combat the widely perceived problem of disengagement from conventional politics among young people. However, subsequent research suggests that, although young people who are already politically active are using online tools for political discussion, new online forums do not appear to have attracted large numbers of new entrants to "conventional" (i.e., party) politics among the young. Moreover, it has been suggested that rules for online conduct designed to keep children safe—telling them not to reveal personal information about themselves, for example, and telling them not to talk to strangers online—tend to discourage online participation in political dialogue.

CONTROVERSIES SURROUNDING BULLETIN BOARD USE

Identity De-Marginalization

Because bulletin boards make it easy for people with unusual or socially stigmatized identities to find each other and discuss their identities—without the embarrassment of face-to-face contact, and often isolated from critical voices—it has been argued that this particular Internet form may sustain and encourage those marginal identities. The Pew survey in 2000 revealed that 18% of online Americans aged 12 to 17 use the Internet to get information about something that is hard to talk about with other people (although this statistic covers a wide variety of online practices, from web page browsing to emailing and chat room use as well as bulletin board use).

Some academics have been quick to praise the support this can provide for groups such as gays and lesbians, but researchers say the same mechanism may be at work in encouraging white supremacists. More recently, media attention has focused on bulletin boards by and for people with eating disorders or those considering self-harm and suicide. It has been argued that these bulletin boards can legitimize and enable those forms of deviance.

Policing

Bulletin boards, like chat rooms, have been portrayed as places where children may face unwanted sexual advances. Studies provide little evidence that this fear is justified, however; a large-scale study of online sexual crimes in the United States suggests that fewer than 5% of sex offenders found their victims through bulletin boards. The relatively public nature of bulletin boards, and the fact that messages once posted normally remain viewable for days afterward, may tend to dissuade potential offenders. Commercial bulletin boards are often policed by paid or volunteer moderators who are on the lookout for antisocial behavior.

INTERNET CONTENT RATING ASSOCIATION (ICRA)

The Internet Content Rating Association (ICRA) is an international nonprofit organization with offices in the United States and the United Kingdom. Its mission is to help users find the content they want and can trust, and to filter out what they do not want for themselves or for their children. ICRA also acts as a forum through which both policy and technical infrastructure are defined to help shape the way that the Web and content distribution channels work.

ICRA has created a unique content description vocabulary that allows Web masters and digital content creators to self-label their content in categories such as nudity, sex, language, violence, other potentially harmful material, and chat. There are context variables such as art, medicine, and news. Thus, a piece of content or a site can be described as having depictions of nudes but in an artistic context. As content creators check the elements in the questionnaire that are present or absent from their websites, a small file is automatically generated using the RDF format, which is then linked to the content on one or more domains.

Users, especially parents of young children, can then use filtering software such as ICRAplus to allow or disallow various types of content. A key point is that ICRA does not rate Internet content; the content providers self-label, and then parents and other concerned adults decide what is or is not appropriate for themselves or their children. ICRA makes no value judgments about sites.

The descriptive vocabulary was drawn up by an international panel and designed to be as neutral and objective as possible. It was revised in 2005 to enable easier application to a wide range of digital content, not just websites.

New developments coming onstream include Quatro, a project funded by the European Union, which will integrate content labels with quality and trust marks. ICRA also intends to launch a service to verify the accuracy of ICRA labels and to provide this information to third-party tools and services, such as search engines.

ICRA's corporate members include AOL, British Telecom, Microsoft, T-Online, and Verizon. ICRA has been supported by the European Union's Internet Action Plan and various trusts and foundations. Through the Associate Membership scheme, individuals can join and support the work of the organization.

INTERNET PORNOGRAPHY, EFFECTS OF

Ever since the emergence of the Internet as a mass medium, scholars in several disciplines have examined the social, psychological, and policy implications of the new medium in diverse content areas. One such area that has attracted an undue degree of attention is pornography. However, although the published research pertaining to pornography in traditional media (e.g., print, television) is voluminous, research on Internet pornography is still in its early stages. Scholarship on the singularity of Internet pornography is meager, and although there has been widespread concern about the probable negative effects of exposure to Internet pornography, there is little experimental evidence to document such potentially negative effects.

Several underlying characteristics of the Internet render both presentation of and exposure to pornography uniquely different in Web-based environments, compared to traditional media venues. First, interactivity (a key attribute of the Web) offers greater control to users in terms of how pornographic materials can be sampled, thus allowing increased customization in online users' consumption of pornography. Second, the multimedia capability of the Web makes it possible to manipulate and disseminate pornographic materials in a variety of different modalities (e.g., text, graphics, video). In fact, some statistics suggest that the multimedia feature is one of the most important features contributing to distribution of pornography as one of the most popular uses of the

Internet. Third, the navigational aspect of the Web raises concerns about how users negotiate Internet pornography. That is, designers of pornographic websites adopt especially unscrupulous strategies and make it very difficult for users to close a browser window when exposed—willingly or unwillingly—to a pornographic website. Such difficulties in navigation could frustrate users and lead them to have negative perceptions of navigational efficiency. Finally, from the user's perspective, the relative anonymity afforded by the Web implies that even otherwise-private individuals can partake of pornography, as it can be easily accessed.

The issue of Internet pornography is especially a concern with adolescents, given that 90% or more of youth in the 12-to-18-year-old range have regular access to the Internet. Scholars have voiced concern that such enhanced access could lead youngsters to seek out sexual materials on the Internet and could have deleterious consequences on adolescent sexual development. Data available from the Youth Internet Safety Survey of 1,501 adolescents in the 10-to-17-year age range suggest that approximately 90% of youth who have reported seeking online pornographic materials are over the age of 14 years, and also that online seekers, as compared to offline seekers, are substantially more prone to feelings of depression or emotional disconnectedness. In addition, 25% of youth reported that they had been inadvertently exposed to online pornography, and a quarter of this segment reported feeling upset upon such exposure, raising concerns that even accidental exposure to Internet pornography can be detrimental to adolescent psychosocial development. In fact, these survey findings are consistent with some experimental results with college-aged youth that suggest that unwanted exposure to Internet pornography can lead users to overestimate the prevalence of Internet pornography and can also lead them to become gloomy and depressed.

Surprisingly, despite the huge debate surrounding the effects of Internet pornography, the amount of published empirical research does not reflect the degree of attention that this topic has attracted. The few studies that have experimentally examined effects of Internet pornography have dealt with adult users. One possible reason for the lack of a protracted stream of experimental research could be the ethical ramifications of exposing adolescents to graphic and explicit sexual materials on the Internet. However, given the large body of findings in traditional media effects research that has examined perceptual differences between exposure to erotic imagery and dehumanizing pornography, one experimental study by Mahood, Kalyanaraman, and Sundar (2000) examined whether college students' perceptions of Internet pornography were contingent not only on the type of pornography (erotica, dehumanizing) but also on the degree of website interactivity (low, medium, high). The findings from this study suggest that participants held less sexual conservatism after exposure to dehumanizing pornography, compared to erotica. Moreover, the interactivity variable also appeared to exert pronounced psychological effects because, irrespective of type of pornographic content, participants exposed to materials with a moderate degree of interactivity expressed the most sex role satisfaction. Finally, an interaction effect revealed that exposure to dehumanizing pornography with medium and high levels of interactivity led to increased acceptance of violence toward women, whereas highly interactive erotica led to less acceptance of violence toward women.

Clearly, given the tremendous public policy implications of the findings thus far, a systematic and nuanced program of research examining the psychosocial effects of exposure to Internet pornography needs to be undertaken.
